Abstract

Aims: The aim of this study was to evaluate the efficacy and safety of 24-month vs. six-month dual antiplatelet therapy (DAPT) among elderly (≥75 years) and non-elderly patients (<75 years) undergoing percutaneous coronary intervention.

Methods and results: The primary efficacy endpoint of the PRODIGY trial was the composite of death, myocardial infarction, or cerebrovascular accident at 24-month follow-up. The key safety endpoint was type 2, 3 or 5 bleeding according to the BARC criteria. Of 1,970 participants, 587 (29.8%) were elderly and had a higher risk of adverse events compared with younger patients. The risk of the primary endpoint was not significantly reduced with 24-month compared to six-month DAPT among both elderly (HR 0.80, 95% CI: 0.55-1.16, p=0.24) and non-elderly patients (HR 1.48, 95% CI: 0.95-2.30, p=0.08), although interaction testing was significant (p=0.036). A 24-month versus six-month DAPT significantly increased the risk of BARC type 2, 3 or 5 bleeding in both older (HR 1.90, 95% CI: 1.06-3.38, p=0.03) and younger patients (HR 2.54, 95% CI: 1.43-4.53, p=0.002, p-interaction=0.48). However, measures of absolute risk difference indicated a less favourable safety profile of prolonged DAPT for older rather than younger patients.

Conclusions: In the PRODIGY trial, prolonging clopidogrel-based DAPT beyond six months in elderly patients increased the risk of bleeding, without affording a significant prevention of ischaemic events.
However, extrapolating such findings to elderly patients is challenging in view of the increased risk of bleeding and ischaemic events occurring in this subgroup. In addition, elderly individuals have been underrepresented among randomised trials that evaluated different durations of DAPT following PCI. The Prolonging Dual Antiplatelet Therapy After Grading Stent-Induced Inthal Hyperplasia Study (PRODIGY) compared a strategy of DAPT extended to 24 months with a shorter course of DAPT up to six months in a broadly inclusive population of PCI patients, with the inclusion of a relatively high proportion of elderly participants.

Therefore, we sought to evaluate the impact of age in modulating the hazard of ischaemic and bleeding events and to investigate the outcomes of 24-month vs. six-month DAPT in elderly (≥75 years) patients vs. younger patients (<75 years) enrolled in the PRODIGY trial.

Methods

Details on study design and primary results of the PRODIGY trial have been reported elsewhere. Briefly, all-comer patients undergoing treatment with a balanced mixture of stents were randomly allocated at 30 days to either up to six months or to 24 months of DAPT. The ethics committees of the participating centres independently approved the protocol and all participants gave written informed consent.

TREATMENT PROTOCOL

All patients received aspirin (80-160 mg orally indefinitely) and clopidogrel (75 mg/day) according to the randomisation scheme as follows: for either up to six months in the short DAPT group or to 24 months in the prolonged DAPT arm, irrespective of the previously implanted stent type or indication for PCI.

Introduction

Elderly individuals account for an increasing proportion of patients with coronary artery disease undergoing percutaneous coronary intervention (PCI), due to the ageing of the population with increased life expectancy. Dual antiplatelet therapy (DAPT) with aspirin and oral P2Y12 adenosine diphosphate receptor inhibitors represents the standard of treatment to prevent new atherothrombotic events after PCI, yet its optimal duration remains controversial. Results from randomised trials and meta-analyses indicate that extended (i.e., >12 months) duration of DAPT is associated with a lower risk of ischaemic events, even though this benefit is partly offset by a higher risk of clinically relevant bleeding. However, extrapolating such findings to elderly patients is challenging in view of the increased risk of bleeding and ischaemic events occurring in this subgroup. In addition, elderly individuals have been underrepresented among randomised trials that evaluated different durations of DAPT following PCI. The Prolonging Dual Antiplatelet Therapy After Grading Stent-Induced Intrathelial Hyperplasia Study (PRODIGY) compared a strategy of DAPT extended to 24 months with a shorter course of DAPT up to six months in a broadly inclusive population of PCI patients, with the inclusion of a relatively high proportion of elderly participants.

Therefore, we sought to evaluate the impact of age in modulating the hazard of ischaemic and bleeding events and to investigate the outcomes of 24-month vs. six-month DAPT in elderly (≥75 years) patients vs. younger patients (<75 years) enrolled in the PRODIGY trial.

STUDY ENDPOINTS

The primary efficacy endpoint of the PRODIGY trial was the composite of death, myocardial infarction (MI), or cerebrovascular accident (CVA), whereas the key safety endpoint included Bleeding Academic Research Consortium (BARC) type 2, 3, or 5 bleeding. Other endpoints included each component of the primary efficacy endpoint, cardiovascular death, stent thrombosis defined on the basis of the Academic Research Consortium criteria, and BARC type 3 or 5 bleeding. Additional safety endpoints were bleeding events adjudicated according to the Thrombolysis In Myocardial Infarction (TIMI) and the Global Utilization of Streptokinase and Tissue Plasminogen Activator for Occluded Arteries (GUSTO) criteria. More detailed definitions of the endpoints have been provided previously. A clinical events committee blinded to treatment allocation adjudicated all efficacy and bleeding events.

STATISTICAL ANALYSIS

Continuous variables are presented as mean±standard deviation and were compared with the Wilcoxon rank-sum test. Categorical variables are expressed as counts and percentages and were compared with chi-square or Fisher’s exact tests as appropriate. We evaluated the effect of age, modulated as a continuous variable, on the risk of ischaemic and bleeding events in the overall population by means of multivariable-adjusted, restricted cubic splines with three knots of the distribution (10th, 50th, and 90th percentiles). The effect of age on clinical events was analysed in the categories of patients <75 vs. ≥75 years by using Cox regression analyses. Both analyses were adjusted for baseline clinical variables associated with the primary efficacy and key safety endpoints at the univariate analysis with a significance level of p<0.20. The efficacy and safety of 24-month DAPT vs. six-month DAPT for elderly (≥75 years) vs. non-elderly (<75 years) patients was evaluated at 24 months. Clinical events were expressed as counts with rates computed according to the Kaplan-Meier method. Cox regression analysis was used to calculate hazard ratios (HRs) with 95% confidence intervals (CIs) and an interaction test was provided to evaluate the effect of treatment in the elderly vs. non-elderly. Sensitivity analyses were conducted to evaluate the efficacy and safety of DAPT from six to 24 months by using a landmark analysis and to assess whether results were consistent by applying the cut-off of 65 years to define the elderly status. In addition, we evaluated the risk of deaths associated or not with MI if they occurred within a seven-day window from MI onset. Risk difference and the number needed to treat for benefit or harm (NNTB or NNTH) with relative 95% CI were also provided in order to account for absolute risk estimates. Finally, the interaction between treatment effect and ageing, modelled as a continuous variable, was analysed with a fractional polynomial interaction. All p-values are two-sided and statistical significance was assumed for p<0.05. All analyses were carried out with Stata Statistical Software, Release 13 (StataCorp LP, College Station, TX, USA).
Results
Of 1,970 participants enrolled in the PRODIGY trial, 587 (29.8%) patients were ≥75 years of age and 1,383 (70.2%) patients were <75 years of age. As shown in Table 1 and Table 2, baseline and periprocedural features were largely comparable within the elderly vs. non-elderly groups between patients assigned to 24-month or six-month DAPT.

EFFECT OF AGEING ON CLINICAL OUTCOMES
There was a direct graded relationship between age and the risks of the primary efficacy or the key safety endpoint, with a steeper increase in the hazard trajectories beyond 70 years of age (Figure 1). A similar direct association between age and bleeding events was observed for BARC type 3 or 5, TIMI minor or major, or GUSTO moderate or severe bleeding (data not shown). When dichotomised, patients with age ≥75 years compared with younger participants had a higher risk of death, MI or CVA and BARC type 2, 3 or 5 bleeding.

EFFICACY OF PROLONGED DAPT AMONG ELDERLY VS. NON-ELDERLY PATIENTS
Figure 2A shows the analysis of efficacy endpoints at two-year follow-up. There was a significant interaction (p=0.036) between age and DAPT duration on primary efficacy endpoints. Table 1 shows the baseline characteristics of patients assigned to different DAPT durations grouped by age.

Table 1. Baseline characteristics.

Values are n (%) or mean±SD. BMI: body mass index; CABG: coronary artery bypass graft; CAD: coronary artery disease; DAPT: dual antiplatelet therapy; HF: heart failure; LV: left ventricular; LVEF: left ventricular ejection fraction; MI: myocardial infarction; NSTE-ACS: non-ST-segment elevation acute coronary syndrome; STEMI: ST-segment elevation myocardial infarction.
SAFETY OF PROLONGED DAPT AMONG ELDERLY VS. NON-ELDERLY PATIENTS

Figure 3A shows the analysis of safety endpoints at two-year follow-up. BARC type 2, 3 or 5 bleeding was significantly increased in both elderly (HR 1.90, 95% CI: 1.06-3.38, p=0.03) and non-elderly patients (HR 2.54, 95% CI: 1.43-4.53, p=0.002; p for interaction=0.48) randomised to 24-month versus six-month DAPT. The NNTH was lower for elderly (NNTH 18; 95%CI: NNTH 119 to NNTH 10) than for non-elderly patients (NNTH 29; 95% CI: NNTH 72 to NNTH 18). Although not significantly increased, bleeding events according to TIMI and GUSTO definitions were numerically higher in patients randomised to 24-month DAPT vs. six-month DAPT. In the analysis between six and 24 months (Figure 3B), the relative risks of BARC type 2, 3 or 5 bleeding were consistently higher in both patients aged ≥75 years (HR 2.73, 95% CI: 1.26-5.89, p=0.01) and patients <75 years (HR 2.73, 95% CI: 1.37-5.44, p=0.004, p for interaction=0.99). The corresponding NNTH for the two groups was 18 (95%CI: NNTH 89 to NNTH 11) and 36 (95%CI: NNTH 107 to NNTH 21), respectively. After six months, moderate or severe
bleeding according to GUSTO criteria was significantly increased in elderly but not in younger patients treated with 24-month DAPT. The corresponding NNTH was NNTH 24 (95%CI: NNTH 78 to NNTH 13) for older vs. NNTH 194 (95%CI: NNTH 198 to NNTH 58) for younger patients. A significant interaction (p=0.007) for the absolute risk difference of moderate or severe GUSTO bleeding was present between older (3.9%, 95% CI: 1.1-6.8%) and younger groups (0.04%, 95% CI: -0.06%-1.5%) after six-month follow-up. By using a cut-off of 65 years, there was no significant interaction (p=0.49) with 24-month vs. six-month DAPT with respect to the primary bleeding endpoint among patients ≥65 years (HR 1.96, 95% CI: 1.23-3.31, p=0.004) vs. those <65 years (HR 2.92, 95% CI: 1.23-6.96, p=0.02).

**INTERACTION BETWEEN AGEING AND TREATMENT EFFECT OF DAPT**

The age-by-treatment interaction evaluated by fractional polynomial analyses was not significant for the primary efficacy (p=0.35) and key safety endpoints (p=0.73). For the composite of death, MI or CVA, the area representing the 95% CI treatment effect crossed the no effect line throughout all ages (Figure 4A). In contrast, the area of treatment effect for the key safety endpoint was above the line of no effect for a wide range of ages, indicating a harmful effect of 24-month over six-month DAPT in terms of bleeding complications for most age values (Figure 4B).

**Discussion**

The main findings of the present analysis of the PRODIGY trial can be summarised as follows.

1) Elderly patients undergoing PCI have a higher risk of ischaemic and bleeding events compared with younger patients, with a similar effect of ageing on the hazards of such events.

2) In both elderly and non-elderly patients, prolonging DAPT for 24 months did not reduce the risk of the primary efficacy endpoint of death, MI or CVA compared with a six-month DAPT.

---

**Figure 2.** Analysis of efficacy outcomes stratified by age. A) Ischaemic events at 24 months. B) Ischaemic events from six to 24 months. CI: confidence intervals; CVA: cerebrovascular accident; DAPT: dual antiplatelet therapy; HR: hazard ratio; MI: myocardial infarction; ST: stent thrombosis
3) A strategy of 24-month DAPT compared with six-month DAPT was associated with a greater risk of the key safety endpoint of BARC type 2, 3 or 5 bleeding in both elderly and non-elderly patients. Although the relative magnitude of treatment effect on bleeding was similar, the absolute risk difference with prolonged DAPT was greater in elderly compared with younger participants.

DAPT is an evidence-based, guideline-recommended, standard of care treatment after PCI\(^1\). Recently, two large randomised trials, DAPT and PEGASUS-TIMI 54 (Prevention of cardiovascular...
events in patients with prior heart attack using ticagrelor compared to placebo on a background of aspirin–thrombolysis in myocardial infarction 54), showed a significant reduction in ischaemic events with long-term DAPT among patients undergoing PCI as well as among high-risk patients with prior myocardial infarction7,9,15,16. Nevertheless, the optimal treatment duration of DAPT remains controversial as the protection afforded by extended DAPT in terms of ischaemic events is counterbalanced by an increase in bleeding complications39. Although the PEGASUS-TIMI 54 trial reported consistent results in terms of the primary ischaemic endpoint according to age, elderly patients represented less than 15% of the overall population41. However, despite being formally not significant (p for interaction=0.09), elderly versus non-elderly patients derived less ischaemic benefit from 90 mg of ticagrelor vs. placebo. At variance, among participants allocated to ticagrelor 60 mg, elderly patients derived a similar magnitude of benefit to non-elderly patients with regard to the primary efficacy endpoint. A treatment-by-age heterogeneity for the primary endpoint according to age has been observed in the ISAR-SAFE (p for interaction=0.03) and IVUS-XPL trials (p for interaction=0.051), favouring the use of short-term DAPT in elderly rather than younger patients47,18. However, the primary endpoint in both trials included a composite of ischaemic and bleeding events, which did not allow complete assessment of the benefit-risk ratio associated with DAPT in elderly patients.

We found that elderly patients experienced a greater risk of both ischaemic and bleeding events, with risk trajectories proceeding similarly with ageing. Such a pattern is similar to that described by Roe and colleagues in a cohort of patients with acute coronary syndrome managed without revascularisation19. Prolonged DAPT did not reduce the risk of ischaemic events among both elderly and non-elderly patients, which is in keeping with the results in the overall finding of the PRODIGY trial. However, interaction testing showed heterogeneity in treatment effect for the primary efficacy endpoint, with a possible harmful effect with 24-month DAPT in non-elderly subjects. In this regard, the higher risk of cardiac instead of non-cardiac death among younger patients randomised to 24-month DAPT, although not related to MI, remains biologically counterintuitive and difficult to explain. Such a finding could also be the result of variable categorisation rather than a direct effect, because the age-by-treatment interaction on a continuous basis was not significant at the fractional polynomial analysis.

Our study provides a nuanced interpretation for the alleged difference in the risk of bleeding associated with DAPT use among elderly patients. We found that prolonged DAPT had a similar effect on the key bleeding endpoint of BARC type 2, 3 or 5 among elderly and non-elderly patients at 24-month follow-up. However, owing to the higher rate of bleeding events, elderly patients had a greater increase in the absolute risk of BARC 2, 3 or 5 bleeding with 24-month DAPT, resulting in a lower NNTH (18 vs. 29). During the period between six and 24 months, the absolute risk difference in BARC 2, 3 or 5 bleeding tended to increase, as well as the difference in the NNTH (18 vs. 36). Taken together, these findings suggest that relative and absolute risks of bleeding should be disentangled in the decision process for DAPT duration in elderly people, by factoring the similar relative risk of bleeding associated with prolonged DAPT with the higher absolute risk difference due to the increased event rate.

Limitations

The results of this study have to be interpreted in the light of several limitations. First, our observations are based on subgroup populations within an overall trial, which failed to show the superiority of prolonged DAPT in the main population. Second, although there is general agreement that people ≥75 years can be defined as “elderly”, ageing is a continuous process and the cut-off of 75 years remains arbitrary. Nevertheless, we tried to accommodate this limitation by evaluating the age-by-treatment interaction also on a continuous basis. Furthermore, a cut-off of 65 years yielded similar results. Third, the group of elderly patients was relatively modest in size, and all the analyses should be considered as hypothesis-generating and exploratory in nature. However, it is noteworthy that the mean age in the PRODIGY trial was the highest across available trials with comparable design. This might explain the differential effect of elderly status on the risk of ischaemic events observed in this study compared with other trials enrolling relatively younger patients.

Fourth, randomisation in the PRODIGY trial was not stratified by age.

Conclusions

In an all-comers population of PCI patients, elderly participants experienced a higher risk of ischaemic and bleeding events compared with their non-elderly counterparts with a comparable effect of ageing on the hazards of such events. Prolonging DAPT for 24 months was not associated with a significantly different risk of the primary efficacy endpoint among elderly and non-elderly patients. However, elderly patients seemed to derive a greater absolute risk of clinically relevant bleeding from prolonged DAPT than younger patients.

Impact on daily practice

Elderly status conveys a higher risk of both ischaemic and bleeding events. Although dual antiplatelet therapy increases the risk of bleeding in both elderly and non-elderly patients, the former group incurs a substantially higher event rate. The efficacy of prolonged dual antiplatelet therapy for the prevention of ischaemic events is not influenced by elderly status.

Conflict of interest statement
