BMJ Open

Primary care physicians’ access to in-house ultrasound examinations across Europe: a questionnaire study

Camilla Aakjær Andersen, Martin Bach B Jensen, Berit Skjødeberg Toftegaard, Peter Vedsted, Michael Harris, Örenäs Research group

ABSTRACT

Objective The overall objective of this study was to examine the differences in ultrasound availability in primary care across Europe.

Design Cross-sectional study.

Setting Primary care.

Participants Primary care physicians (PCPs).

Primary and secondary outcomes measures The primary aim was to describe the variation in in-house primary care ultrasound availability across Europe using descriptive statistics. The secondary aim was to explore associations between in-house ultrasound availability and the characteristics of PCPs and their clinics using a mixed-effects logistic regression model.

Results We collected data from 20 European countries. A total of 2086 PCPs participated, varying from 59 to 446 PCPs per country. The median response rate per country was 24.8%. The median (minimum–maximum) percentage of PCPs across Europe with access to in-house abdominal ultrasonography was 15.3% (0.0%–98.1%) and 12.1% (0.0%–30.8%) had access to in-house pelvic ultrasonography with large variations between countries. We found associations between in-house abdominal ultrasonography availability and larger clinics (OR 2.5, 95% CI 1.2 to 4.9) and clinics with medical doctors specialised in areas, which traditionally use ultrasonography (OR 2.1, 95% CI 1.1 to 3.8). Corresponding associations were found between in-house pelvic ultrasonography availability and larger clinics (OR 1.9, 95% CI 1.3 to 2.7) and clinics with medical doctors specialised in areas, which traditionally use ultrasonography (OR 3.0, 95% CI 1.8 to 5.1). Additionally, we found a negative association between urban clinics and in-house pelvic ultrasound availability (OR 0.5, 95% CI 0.2 to 0.9)."
are organised.\textsuperscript{12,13} GPs with access to diagnostic tests have been found to diagnose, treat and refer patients more appropriately.\textsuperscript{14} Hence, in-house availability of ultrasonography in primary care may improve patient care.

The availability and use of ultrasound examinations in primary care differs between countries: experts have previously estimated that the proportion of primary care users across Europe varies from less than 1% to 67%,\textsuperscript{15} and in-house availability of ultrasonography varies from 4% to 58% in the Nordic countries alone.\textsuperscript{16} We do not know what determines this variation or the extent to which PCP and clinic characteristics are associated with the likelihood of in-house availability of ultrasonography.

The aims of this study were to describe the variation in in-house primary care ultrasonography availability across Europe, and the association between this availability and the characteristics of PCPs and their clinics.

**MATERIALS AND METHODS**

Our study was a secondary analysis of data from the Örenäs survey.\textsuperscript{17} The Örenäs survey investigated the influence of health system factors on the way that European PCPs manage their patients. As well as collection of demographic data, there was collection of data on PCPs’ in-house access to diagnostic abdominal and pelvic ultrasonography. In the present study, this access is compared with the demographic data. A predefined protocol was developed prior to accessing the data (see online supplementary file 1).

The questionnaire was piloted twice by PCPs in 16 Örenäs Research Group centres. Translations of the questionnaire into local languages were made where these languages were not English. Translation was validated by back-translation to assess semantic and conceptual equivalence and is described elsewhere.\textsuperscript{18} The questionnaires were put online using SurveyMonkey (SurveyMonkey, California, USA).

**Participants and recruitment**

The study was conducted in 25 Örenäs Research Group centres in 20 countries across Europe. In some countries, more than one Örenäs Research Group was keen to collect data for this study. In those countries, each group recruited participants on a regional basis, so there was no risk of geographical overlap.

Subjects were eligible for the survey if they were GPs or had specialist training, but worked in the community and could be accessed directly by patients without referral.

Each Örenäs Research Group local lead emailed a survey invitation to the PCPs in their local health district, with the aim of recruiting at least 50 participants. The Örenäs Research Group local leads were asked to recruit a varied sample with regards to gender, years since graduation, site of practice (urban, rural, remote) and size of practice. Consent was implied by agreeing to take part in the survey.

**Data collection**

**Access to ultrasonography**

Participants were asked if abdominal or pelvic diagnostic ultrasonography was available to them in (1) their own practice, (2) at their request outside their practice, or (3) not directly available to them, or only available via a specialist. We divided this into Access to in-house abdominal ultrasonography (AbdUS) and No access to in-house AbdUS (including access at their request outside their practices, not directly available to them or only available via a specialist) and correspondingly: Access to in-house pelvic ultrasonography (PelUS) and No access to in-house PelUS. Hence, the variables In-house access to AbdUS and In-house access to PelUS included direct access to diagnostic ultrasonography in respondents’ own practices.

**Countries included**

The survey was circulated in 20 countries across Europe: Bulgaria, Croatia, Denmark, England, Finland, France, Germany (Essen and Munich), Greece, Israel, Italy, Netherlands, Norway, Poland (Bydgoszcz and Białystok), Portugal, Romania, Scotland, Slovenia, Spain (Barcelona, Galicia and Mallorca), Sweden and Switzerland.

**Characteristics of the PCPs**

PCPs were characterised by Gender, male/female; Level of seniority, <10 years of experience as a medical doctor and ≥10 years (including 10–19, 20–29, 30–39, 40 years or over); and Specialty of the PCP, GP/not GP (including specialists in ear, nose and throat, internal/general medicine, obstetrics/gynaecology, oncology, orthopaedics, paediatrics, other).

**Characteristics of the clinics**

PCPs’ clinics were characterised by location (self-defined by participants): urban or non-urban (including rural, island, mixed), and clinic size (number of PCPs in the clinic: solo (1 PCP), small (2–5 PCPs), medium (6–9 PCPs) and large (10 or more PCPs)).

In the survey, participants were asked if they had colleagues qualified in different specialities (ear, nose and throat, internal/general medicine, obstetrics/gynaecology, oncology, orthopaedics, paediatrics or other). We assessed the proportion of PCPs with colleagues in their clinic who were qualified in a specialty in which ultrasonography is traditionally used (where clinical guidelines for use and educational programmes exist for the specialty). We estimated this as the Proportion of PCPs having specialist in internal medicine in their clinic and the Proportion of PCPs with an obstetrician/gynaecologist colleague in their own clinic. Finally, we noted any free-text comments that the PCPs had a Sonographer/radiologist colleague in the clinic, elaborated under the reply ‘other’. Free text comments were translated using Google Translate.

**Ethics**

Other countries’ study leads either achieved local ethical approval or gave statements that formal ethical approval
was not needed in their jurisdictions (see online supplementary file 2).

Patient and public involvement
Patients were not involved in this study.

Statistics
We calculated the proportions of PCPs with in-house access to AbdUS or PelUS for each of the characteristics. A mixed-effects logistic regression model was used to test associations between access to in-house ultrasonography and the characteristics of the PCP and clinic. To avoid estimating a large number of parameters, the mixed-effects logistic regression model included fixed effects for all variables and random effects for variables dependent on country. This model allowed us to look across countries and captured the country effect without losing too many degrees of freedom. To identify variables dependent on country, we used multiple logistic regression including main effects and interactions with country between each of the other main-effects variables. Backwards model selection was used to eliminate insignificant terms from the model. Missing data were considered completely random and ignored in the analysis. The model was estimated in STATA V.15.0 (StataCorp, College Station, Texas, USA). Statistical significance was defined as a p value ≤0.05.

Results
A total of 2086 PCPs participated, varying from 59 to 446 PCPs per country. The median response rate per country was 24.8% (range, 7.1%–65.6%). There was a large between-country variation in the variables: 61.7% (range, 17.2%–88.0%) were female and 38.3% (range, 12.0%–82.8%) male; 96.9% (range, 81.6%–100%) were specialised as GPs, and 16.0% (range, 1.6%–55.9%) had less than 10 years’ experience as a medical doctor. The clinics were mainly urban: 59.7% (range, 28.6%–93.1%); 13.8% (range, 0.0%–55.2%) were solo practices, 39.0% (range, 7.9%–67.9%) small, 20.9% (range, 3.2%–55.5%) medium and 26.2% (range, 0.0%–70.1%) large. Between-country variations are shown in table 1.

Using multiple logistic regression, we identified interactions between country and variables describing the characteristics of the clinics (Location, Clinic size, In-house colleague qualified in a medical specialty which traditionally uses ultrasonography). There were no interactions between country and variables describing the characteristics of the PCP (Gender, Level of seniority, Specialty of the PCP). As a result, we applied a mixed-effects logistic regression model that included fixed effects for all variables and random effects for variables describing the characteristics of the clinics. Visual inspection of the country-specific random effects showed concordance between AbdUS and PelUS, indicating comparable parameter estimates and that the country effects were modelled appropriately.

Hence, we applied the same model structure to both AbdUS and PelUS.

Twenty-one observations from nine different countries were excluded due to an unreported number of PCPs working in the clinic. We chose to consider these missing data random, as we believed that the likelihood of the PCP answering the question about the number of PCPs working in the clinic was independent from the PCP’s access to in-house AbdUS or PelUS.

Variation in access to in-house ultrasonography between countries and between regions within a country
The median percentage of PCPs across Europe with access to in-house AbdUS was 15.3% (range, 0.0%–98.1%) and 12.1% (range, 0.0%–30.8%) had access to in-house PelUS. However, there was large variation between countries (table 1 and figure 1).

In-house access to AbdUS was very common in Germany (98.0%), followed by Slovenia (41.4%) and Switzerland (40.6%). In-house access to AbdUS was least available in England (0%), Croatia (1.5%) and Denmark (1.9%). Compared with AbdUS, in-house access to PelUS was less common, with the highest proportions found in Finland (30.8%), Slovenia (21.5%) and France (20.3%). In contrast, it was uncommon in England (0%), Croatia (1.5%) and Bulgaria (3.4%).

In addition, there were large differences in access to in-house AbdUS between the two Polish regions (Bialystok 17.9 and Bydgoszcz 57.9%) and the three Spanish regions (Mallorca 3.8%, Galicia 9.6% and Barcelona 43.7%), whereas there was little difference between the two German regions (Munich 96.3% and Essen 98.7%). There was also a large variation in the proportions of clinics with access to in-house PelUS in Germany (Essen 1.3% and Munich 11.1%), Poland (Bialystok 8.4% and Bydgoszcz 33.3%) and Spain (Galicia 4.8%, Mallorca 6.0% and Barcelona 25.8%).

PCP characteristics and in-house access to ultrasonography
We found no statistically significant associations between the PCP characteristics and in-house access to AbdUS or PelUS (table 2).

Clinic characteristics and in-house access to ultrasonography
Larger practices were significantly associated with higher levels of both in-house access to AbdUS (OR 2.5, 95% CI 1.2 to 4.9) and PelUS (OR 1.9, 95% CI 1.3 to 2.7), while we found a negative association between a small practice size and PelUS (OR 0.6, 95% CI 0.4 to 0.9) compared with solo practices. We also found a negative association between urban location and with higher levels of PelUS (OR 0.5, 95% CI 0.2 to 0.9). Having an in-house colleague specialised in a medical field which traditionally uses ultrasonography was found to be positively associated with having access to in-house AbdUS (OR 2.1, 95% CI 1.1 to 3.8) and PelUS (OR 3.0, 95% CI 1.8 to 5.1); 36.1% of PCPs with in-house AbdUS had an internal medicine colleague in their clinics, and 29.7% of PCPs using ultrasonography was found to be positively associated with...

*Absolute numbers given in each variable (n) do not add up to the total number of participants in each country (N) due to missing values.

AbdUS, abdominal ultrasonography; GP, general practitioner; N (%), number of participants in each country (response rate); n, absolute value in each variable; PCP, primary care physician; PelUS, pelvic ultrasonography.

### Discussion

**Principal findings**

We found large variations across Europe in primary care access to in-house ultrasonography. The majority of PCPs do not have diagnostic ultrasonography available in their own clinics. We found some associations between in-house ultrasonography and the clinic and the likelihood of having in-house ultrasonography, including a significant association between increased likelihood and clinics with more than 10 PCPs, and with clinics with colleagues specialised in internal medicine and gynaecology/obstetrics. We also found an increased likelihood of having in-house access to PelUS among non-urban clinics.

### Strengths and limitations

A strength of this study is the large number of participating countries, with a response rate higher than previous studies. Moreover, the survey recruitment strategy was not biased by access to in-house ultrasonography since the overall aim of the survey was to explore PCPs' decision-making with regard to referring patients who may have cancer for further investigation. However, selection bias may have been introduced by both the recruitment methods and the survey distribution, and the participants may not be representative of the whole population of PCPs in each country. In most of the countries involved, the survey was only circulated in one specific region, and in those countries where regional data was available, we found inter-regional variation in ultrasonography access. This means that regional differences may have influenced our results. Using secondary data may introduce information bias. In our study, we explored whether having access to in-house ultrasonography was associated with having a colleague specialised in a medical field that traditionally uses ultrasonography. However, selection bias may have been introduced by only including PCPs who have access to in-house ultrasonography. Finally, the participant's free-text answers may be underestimated.
all possible associations between the measured variables. However, the nature of our sample may have caused limitations as some associations may have been missed due to lack of power, and some variables may have been eliminated during the fitting of the model due to lack of power. However, the aim of this study was a preliminary assessment and more research is needed to determine the importance of different factors in relation to in-house ultrasonography access.

Comparison with existing literature

In a survey from 2016, ultrasound experts estimated the proportion of GPs using ultrasonography to vary from less than 1% in Austria, Catalonia, Denmark and Sweden to 45% in Germany. Our study confirmed significant variation, although our proportions were higher (figure 1). This may be caused by selection bias or by the difference between estimations by experts and measured proportions. Furthermore, the previous study estimated PCPs’ use of ultrasonography, while our study measured PCPs’ actual access to in-house ultrasonography. Access to ultrasonography in the Scandinavian countries was explored using QUALICOPC data from 2012. This found higher levels of access than our study (Denmark 11.3%, Finland 57.7%, Norway 16.7%, Sweden 4.1%). This may be because the QUALICOPC study asked about access to any type of ultrasound, not specifically diagnostic abdominal or pelvic ultrasonography; hence, therapeutic ultrasound used for musculoskeletal conditions and A-mode ultrasound may have been included in those data.

European between-country variations have also been described for other diagnostic tests in primary care; thus, variations in access to in-house ultrasound may be caused by national differences in the organisation of primary care. For example, the high proportion in Finland may be explained by larger healthcare centres with more advanced equipment, whereas in Germany PCPs are taught how to use ultrasonography for abdominal examinations. Whether the gate-keeper function that PCPs have in some countries, the specialty training system for PCPs, the PCP’s ultrasound training or the waiting time to see a specialist is important is unclear since we did not collect data on these issues.

Financial aspects may also be important. In countries where PCPs are largely self-employed, they need to pay for ultrasound equipment themselves. In addition, ultrasonography is a time-consuming examination, and differences in remuneration for performing ultrasonography may be of particular importance. Workload for the PCP may also be an important factor since research has shown considerable variation in the number of consultations per day and the consultation length.

Distance from the secondary care provider has previously been found to be of importance for in-house PelUS, and our study also found an association between in-house PelUS availability and non-urban practices. Associations between technology and larger clinics have previously been described. However, the association between larger clinics and access to ultrasonography

n (%)=absolute number and percentage of dependent variable for each independent variable.
*ORs with 95% CI calculated using a mixed-effects logistic regression model including fixed effects for all variables and random-effects variables interacting with country.
†P values for adjusted OR
‡An in-house colleague who had specialised in internal medicine (for AbdUS) or gynaecology or obstetrics (for PelUS) was considered to have qualified in a medical specialty that traditionally uses ultrasonography.
AbdUS, access to in-house abdominal ultrasonography; PCP, primary care physician; PelUS, access to in-house pelvic ultrasonography.

may also be explained by the multidisciplinary nature of some larger clinics. Some countries, for example, Finland, Spain, Sweden and England, have multidisciplinary teams working in primary care, while others, for example, Switzerland, Romania, Norway, Germany, Denmark and Bulgaria, tend to have less staff. In our study, we found an association between in-house ultrasonography availability and having a colleague in the clinic who was qualified in a medical specialty which traditionally uses ultrasonography. However, we do not know if these colleagues were performing ultrasonography examinations, and most PCPs did not have such colleagues. As AbdUS and PelUS can be performed by PCPs with different educational backgrounds and correspondingly different levels of ultrasound training, quality assurance of ultrasound examinations performed in primary care is important.

Implications
Several factors may influence the availability of ultrasonography in primary care across Europe, including who performs the examinations and the organisation of healthcare systems. This study may generate hypotheses for future studies that further explore national factors. As ultrasonography is disseminating into primary care, knowledge about the influence that these factors have is important to guide the implementation process and to secure appropriate use of the technology.

CONCLUSIONS
PCPs’ access to in-house ultrasonography in primary care across Europe varied from 0% to 98% for AbdUS, and 0% to 31% for PelUS. While in-house ultrasonography might be an important tool to ensure faster and more correct diagnosis in primary care, in every country except Germany it was available to less than half of our PCP respondents. As evidence continues to support point-of-care ultrasonography as a front-line test, implementation strategies for the increased availability of the technology in primary care are needed. Several factors might influence PCPs’ access to in-house diagnostic ultrasonography, and future research should focus on exploring these factors further.

Acknowledgements We would like to thank Associate Professor, PhD Torben Tvedebrink for statistical assistance, the Örenäs Research Group collaborators who collected the survey data and all the PCPs who completed the survey.

Contributors CAA, MH, BST, PV and MBBJ all participated in designing the study. CAA performed the analysis and wrote the first draft of the article in collaboration with MH and MBBJ. All authors participated in the review process and made significant contributions to the final version of the article. The following Örenäs Research Group members participated in designing and/or piloting the study, and
are non-author collaborators: Isabelle Aubin-Augier, Université Paris Diderot, France; Joseph Azuri, Tel Aviv University, Israel; Matte Brekke, University of Oslo, Norway; Krzysztof Buczkowski, Nicolaus Copernicus University, Poland; Nicola Buono, National Society of Medical Education in General Practice (SNaMID), Italy; Emiliana Costug, Iuliu Hatieganu University of Medicine and Pharmacy, Romania; Geert-Jan Dinant, Maastricht University, Netherlands; Magdalena Esteva, Majorca Primary Health Care Department, Palma Mallorca, Spain; Gergana Foreva, Medical Center BROD, Bulgaria; Svjetlana Gašparović-Babić, The Teaching Institute of Public Health of Primorsko-goranska County, Croatia; Robert Hoffman, Tel Aviv University, Israel; Eva Jakob, Centro de Saúde Sarría, Spain; Tuomas Koskela, University of Tampere, Finland; Mercè Maroño-Castillejo, Institut Catalá de la Salut, Barcelona, Spain; Peter Murchie, University of Aberdeen, Scotland; Ana Luisa Neves, Imperial College, UK and University of Porto, Portugal; Davorina Petek and Marija Petek Ster, University of Ljubljana, Slovenia; Jolanta Sawicka-Powerza, Medical University of Białystok, Poland; Antonius Schneider, Technische Universität München, Germany; Emmanouil Smyrnakis, Aristotle University of Thessaloniki, Greece; Sven Streit, University of Bern, Switzerland; Hans Thulesius, Lund University, Sweden; Birgitta Weltermann, University of Bonn, Germany.

Funding The authors have not declared a specific grant for this research from any funding agency in the public, commercial or not-for-profit sectors.

Competing interests None declared.

Patient consent for publication Not required.

Ethics approval Ethical approval for the original study was given by the University of Bath Research Ethics Approval Committee for Health (approval date: 24 Nov 2014; REACH reference no. EP 14/15 66).

Provenance and peer review Not commissioned; externally peer reviewed.
