## Supplementary Material

## 1 ARCHITECTURE DETAILS

### 1.1 Base Architecture and Adaptations

We used a common base architecture to analyze the different uncertainty estimation methods. Its building blocks, dimensions, and channel numbers are listed in Table S1. The 2D blocks consist of a $1 \times 3 \times 3$ convolution, dropout ( $p=0.05$ ), batch normalization, and ReLU activation. In the 3D blocks, the $1 \times 3 \times 3$ convolution is followed by a $3 \times 1 \times 1$ convolution, expressing the 3 D convolution by a separable axial in-plane (2D) and out-plane (1D) convolution. In-plane and out-plane convolutions use same and valid border modes, respectively. Max-pooling and upsampling are performed in-plane $(1 \times 2 \times 2)$ where the latter is implemented as trilinear interpolation. The input of the network is a subvolume of five consecutive axial slices of all four MR images. Only subvolumes containing information of the skull-stipped brain were used for training. If required, the subvolumes at the upper- and lowermost slices are zero-padded. The output consists of a separate probability map for each of the three hierarchical labels (WT, TC, ET) and corresponds to the subvolume's center slice.

| Building block | Dimensions $(\mathrm{Z} \times \mathrm{Y} \times \mathrm{X})$ | Channels |
| :--- | :---: | :---: |
| Input | $5 \times 240 \times 240$ | 4 |
| 2D block, 3D block, max-pool | $3 \times 120 \times 120$ | 32 |
| 2D block, 3D block, max-pool | $1 \times 60 \times 60$ | 64 |
| 2D block, 2D block, max-pool | $1 \times 30 \times 30$ | 128 |
| 2D block, 2D block, max-pool | $1 \times 15 \times 15$ | 256 |
| 2D block, 2D block | $1 \times 15 \times 15$ | 256 |
| Upsample, 2D block, 2D block | $1 \times 30 \times 30$ | 128 |
| Upsample, 2D block, 2D block | $1 \times 60 \times 60$ | 64 |
| Upsample, 2D block, 2D block | $1 \times 120 \times 120$ | 32 |
| Upsample, 2D block, 2D block | $1 \times 240 \times 240$ | 32 |
| 1x1 convolution | $1 \times 240 \times 240$ | 3 |
| Channel-wise sigmoid | $1 \times 240 \times 240$ | 3 |

Table S1. Building blocks, dimensions, and channel numbers of the base architecture. 2D blocks consist of $1 \times 3 \times 3$ convolution, dropout ( $p=0.05$ ), batch normalization, and ReLU activation. 3D blocks insert an additional $3 \times 1 \times 1$ convolution after the initial convolution. Each output channel corresponds to one of the hierarchical labels (whole tumor, tumor core, and enhancing tumor).

Modifications of this base architecture are required for the different dropout strategies (center/ $+M C$, center low $/+M C$, and concrete/ $+M C$ ) and for the aleatoric method. The center strategies apply dropout directly before the max-pooling and after the upsampling instead in each 2D and 3D block. Center/ $+M C$ does this for all pooling/upsampling levels and center low/ $+M C$ only for the two lowermost levels (i.e. at dimensions $1 \times 60 \times 60$ and $1 \times 30 \times 30$ ). Concrete $/+M C$ replaces all dropout from the base architecture by concrete dropout. The modification required for the aleatoric method are three additional outputs (six in total) corresponding to the variance maps of each hierarchical label. These additional outputs possess a separate $1 \times 1$ convolution layer and do not use any sigmoid classification layer. Figure $\$ 1$ shows the structure of the base architecture and the modifications for the individual uncertainty estimation methods.

Figure S1. Structure of the base architecture including the modifications for the individual uncertainty estimation methods. The particularities for each method are color-coded.

### 1.2 Auxiliary Network Architectures

The auxiliary methods use the segmentations obtained from the base architecture (described in Section 1.1) to learn to predict the segmentation errors. To do so, auxiliary segm. employs a architecture equal to the base architecture but operates solely on slices (no 3D blocks) and consists of an input of seven channels. These channels correspond to the four MR images and three label maps (WT, TC, ET) produced by the base segmentation architecture. Table $\$ 2$ lists the building blocks, dimensions, and channel numbers of the auxiliary feat. architecture. It is a lot simpler than the auxiliary segm. architecture since it employs direct feature information, in contrast to the label maps, of the base segmentation network. It consists of three consecutive 2D blocks, each comprising a $1 \times 1$ convolution, batch normalization, and ReLU activation. Figure $\mathbf{S 2}$ shows the structure of both auxiliary architectures.

Besides possessing different architectures, the two auxiliary methods also differ in the computation of their training data. While auxiliary feat. was trained on the errors that the segmentation network made on the training data, auxiliary segm. used the segmented label maps of a five-fold cross-validation of the training set. This cross-validation ensures that auxiliary segm. is trained on errors produced on held out (test) splits of the training data rather than training set errors.

As for the base architecture, we used Adam optimizer (learning rate: $10^{-4}, \beta_{1}: 0.9, \beta_{2}: 0.999, \varepsilon: 10^{-8}$ ) to optimize the cross-entropy loss in mini-batches of 24 .

| Building block | Dimensions $(\mathrm{Y} \times \mathrm{X})$ | Channels |
| :--- | :---: | :---: |
| Input | $240 \times 240$ | 32 |
| 2D block | $240 \times 240$ | 32 |
| 2D block | $240 \times 240$ | 32 |
| 2D block | $240 \times 240$ | 32 |
| 1x1 convolution | $240 \times 240$ | 3 |
| Channel-wise sigmoid | $240 \times 240$ | 3 |

Table S2. Building blocks, dimensions, and channel numbers of the architecture used for auxiliary feat. method. 2D blocks consist of $1 \times 3 \times 3$ convolution, batch normalization, and ReLU activation. Each output channel corresponds to the uncertainty of one of the hierarchical labels (whole tumor, tumor core, and enhancing tumor)

Auxiliary segm.

Auxiliary feat.

Figure S2. Structure of the auxiliary segm. and auxiliary feat. architectures. The modifications of the auxiliary segm. architecture compared to the base architecture are shown in brown.

## 2 AGGREGATION METHODS

### 2.1 Prior Knowledge Aggregation

We used three types of voxel-wise uncertainty weighting during aggregation with prior knowledge: (a) boundary weighting, (b) distance weighting, and (c) volume weighting. Boundary weighing excludes uncertainties at the segmentation boundary, which we defined as a three-voxel band (i.e., boundary and voxels next to the boundary). Distance weighting weights the uncertainties by the Euclidean distance to the segmentation boundary in voxels (i.e., distance increases by one for each voxel). Volume weighting inversely weights the overall uncertainty by the volume of the segmentation. We combined these three weighting methods with three simple aggregation operations: mean, sum, and logsum aggregation. Table $\$ 3$ lists the nine combinations we considered.
\(\left.$$
\begin{array}{ll}\hline \text { Type } & \text { Description } \\
\hline \text { mean } & \begin{array}{l}\text { Average of the voxel-wise uncertainties of a subject } \\
\text { logsum } \\
\text { volume weighted sum }\end{array} \\
\text { masked mean the voxel-wise log uncertainties of a subject }\end{array}
$$ \quad \begin{array}{l}Sum of the voxel-wise uncertainties divided by the <br>
segmentation volume <br>
Mean of the uncertainties masked by the <br>

segmentation boundary\end{array}\right]\)| Logsum of the uncertainties masked by the |
| :--- |
| segmentation boundary |

Table S3. List of the nine different uncertainty aggregations with prior knowledge.

### 2.2 Automatically Extracted Features

As mentioned in the main text, we used PyRadiomics (version 2.2.0) to automatically extract features from the voxel-wise uncertainty estimates. We defined the region of interest by thresholding the uncertainty with the thresholds that achieved the best validation set performance for the U-E metric (same thresholds as used to calculate the U-E metric). We extracted the 102 default PyRadiomics features consisting of 14 shape features, 18 first-order statistic features, 24 gray leve $\left.\right|^{1}$ co-occurrence matrix features, 16 gray level run length matrix features, 16 gray level size zone matrix features, and 14 gray level dependence matrix features. The default settings were used for the extraction (image type: original, bin width: 25). For details on the features groups and individual features we refer to the PyRadiomics website ${ }^{2}$,

### 2.3 Random Forest Regressor

To predict the Dice coefficient of the segmentations from the uncertainty features (aggregated by prior knowledge or automatically extracted), we used the random forest regressor from scikit-learn ${ }^{3}$ (version 0.21 .2 ) with the default settings (n_estimators: 10, criterion: 'mse' max_depth: None). To train the random forest, we applied a five-fold cross-validation on the 160 subjects of the test set and repeated this process five times. The final prediction and features importances were obtained by averaging the results of the five repetitions. Note that we purposely did not tune any parameters in this cross-validation.

## 3 VISUAL EXAMPLES OF UNCERTAINTY ESTIMATES

Figure S 3 and S 4 show the uncertainty estimates for the tumor core and enhancing tumor labels produced by the selected methods on underconfident, overconfident, and well-calibrated subjects.

## 4 ADDITIONAL VOXEL-WISE METRICS

We computed additional metrics that complement the expected calibration error (ECE) and the uncertaintyerror overlap (U-E) from the main text.

ACE. The average calibration error (ACE) aims at distilling the information of a reliability diagram into one scalar value. In contrast to the ECE, the absolute calibration error between the confidence and accuracy bins, $c_{m}$ and $a_{m}$ respectively, is equally weighted in the ACE. With $M$ being the number of non-empty bins, the ACE is given by

$$
A C E=\frac{1}{M} \sum_{m}^{M}\left|c_{m}-a_{m}\right|
$$

and ranges from 0 to 1 , where a lower value represents a better calibration. As for the ECE, we report the mean subject ACE.

AUC-PR. Complementary to the uncertainty-error overlap, we also report the area under the curve of the precision-recall curve (AUC-PR). The AUC-PR summarizes the precision and recall performance of the overlap between uncertainty and segmentation error at different thresholds. We used the same thresholds as for determining the best U-E. The AUC-PR ranges from 0 to 1 , where higher AUC-PR values indicate better performance.

[^0]|  | WT |  | TC |  | ET |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  | ACE\% | AUC-PR | ACE\% | AUC-PR | ACE\% | AUC-PR |
| baseline | 16.995 | 0.249 | 17.905 | 0.243 | 19.951 | 0.23 |
| concrete | 15.65 | 0.251 | 17.77 | 0.253 | 19.118 | 0.229 |
| center low | 15.569 | 0.251 | 17.667 | 0.25 | 19.493 | 0.234 |
| center | 19.886 | 0.238 | 18.998 | 0.247 | 19.532 | 0.22 |
| baseline + MC | 16.505 | 0.248 | 16.997 | 0.24 | 18.598 | 0.221 |
| concrete + MC | 15.571 | 0.249 | 17.554 | 0.251 | 18.759 | 0.227 |
| center low + MC | 15.346 | 0.244 | 17.523 | 0.248 | 19.076 | 0.231 |
| center + MC | $\mathbf{1 3 . 5 5 3}$ | 0.205 | 17.257 | 0.213 | 17.827 | 0.19 |
| ensemble | 15.702 | 0.24 | 16.719 | 0.23 | 18.164 | 0.219 |
| aleatoric | 15.518 | 0.004 | $\mathbf{1 0 . 4 1 2}$ | 0.202 | $\mathbf{1 4 . 5 1}$ | 0.029 |
| auxiliary segm. | 17.677 | 0.298 | 20.252 | 0.249 | 21.416 | 0.284 |
| auxiliary feat. | 17.278 | $\mathbf{0 . 3 0 1}$ | 17.918 | $\mathbf{0 . 2 7 6}$ | 21.033 | $\mathbf{0 . 3 4 4}$ |

Table S4. Performances of the different uncertainty estimation methods in terms of average calibration error (ACE) and area under the curve of the precisionrecall curve (AUC-PR). Both metrics range from 0 to 1 , but the ACE is reported in \%. Lower ACE values are better as well as higher AUC-PR values. Bold values indicate best performances. Horizontal separations group types of uncertainty methods and WT, TC, and ET indicate the tumor regions whole tumor, tumor core, and enhancing tumor.

Table S4 lists the results obtained for the ACE and AUC-PR metrics. The main differences of the ACE results compared to the ECE results (see Table 1 in the main text) are the good ACE results obtained by the aleatoric method. This is mainly due to the empty bins, which are ignored for the ACE. We also observe good ACE results for the center $+M C$ method. We expect this to be due to a more equal distribution of the samples among the bins compared to the other methods. In terms of AUC-PR we observe a benefit of the auxiliary methods. The reason might be related to their training, in which are optimized to find the overlap between the automated segmentation and the reference segmentation. Also, the $+M C$ versions consistently perform worse than their counterparts.

## 5 DETAILS ON AGGREGATION RESULTS

### 5.1 ROC Curves

Figure $\mathrm{S5}$ shows the receiver operating characteristic (ROC) curves of the uncertainty estimation methods for the three aggregation methods and three tumor regions.

### 5.2 Metric Values

Table S5 presents the details of the obtained failure detection (AUC-ROC, Youden's accuracy) and the correlation to the Dice coefficient (Spearman's rank correlation) for the three aggregation methods: (a) mean aggregation, (b) aggregation with prior knowledge, and (c) aggregation with automatically extracted features.
