(Received 20 December 2021; accepted 16 February 2022; published 14 March 2022)

Higher-order hadronic corrections to the anomalous magnetic moment of the muon have been evaluated including next-to-next-to-leading-order insertions of hadronic vacuum polarization and next-to-leading-order corrections to hadronic light-by-light scattering. This leaves a set of mixed leptonic and hadronic corrections in the form of double-bubble topologies as the only remaining hadronic effect at  $\mathcal{O}(\alpha^4)$ . Here, we estimate these contributions by analyzing the respective cuts of the diagrams, suggesting that the impact is limited to  $\lesssim 1 \times 10^{-11}$  and thus negligible at the level of the final precision of the Fermilab  $g - 2$  experiment.

DOI: 10.1103/PhysRevLett.128.112002

**Introduction.**—The main uncertainty in the standard-model prediction for the anomalous magnetic moment of the muon [1–28]

$$a_\mu^{\text{SM}} = 116\,591\,810(43) \times 10^{-11} \quad (1)$$

comes from the leading hadronic corrections: hadronic vacuum polarization (HVP) at  $\mathcal{O}(\alpha^2)$  in the expansion in the fine-structure constant  $\alpha$  and hadronic light-by-light scattering (HLBL) at  $\mathcal{O}(\alpha^3)$ . In addition, to achieve the required precision, higher-order corrections that include the insertion of the leading-order (LO) hadronic matrix elements have to be considered at next-to-leading order (NLO) [29] and even next-to-next-to-leading order (NNLO) [13]. Reference [1] includes the following contributions:

$$\begin{aligned} a_\mu^{\text{HVP,LO}} &= 6931(40) \times 10^{-11} \quad \mathcal{O}(\alpha^2) \quad [6-12], \\ a_\mu^{\text{HVP,NLO}} &= -98.3(7) \times 10^{-11} \quad \mathcal{O}(\alpha^3) \quad [11], \\ a_\mu^{\text{HVP,NNLO}} &= 12.4(1) \times 10^{-11} \quad \mathcal{O}(\alpha^4) \quad [13], \\ a_\mu^{\text{HLBL}} &= 90(17) \times 10^{-11} \quad \mathcal{O}(\alpha^3) \quad [14-27, 30-35], \\ a_\mu^{\text{HLBL,NLO}} &= 2(1) \times 10^{-11} \quad \mathcal{O}(\alpha^4) \quad [28], \end{aligned} \quad (2)$$

where we indicated the order in  $\alpha$  at which each term arises. (We do not address possible tensions between lattice and data-driven determinations of the HVP contribution,

see, e.g., Refs. [36–41]. Note that for HLBL scattering there is good agreement between phenomenology and lattice QCD, see Refs. [42–49] for some recent developments.) These numbers should be compared to the current experimental world average [50–54]

$$a_\mu^{\text{exp}} = 116\,592\,061(41) \times 10^{-11}, \quad (3)$$

as well as the final precision  $\Delta a_\mu^{\text{exp}}[\text{E989}] = 16 \times 10^{-11}$  projected for the Fermilab experiment [55]. Further experiments are planned at J-PARC [56] and, potentially, at the proposed high-intensity-muon-beam facility at PSI [57], but in either case it appears challenging to move beyond a precision of  $1 \times 10^{-10}$ .

The comparison to Eq. (2) shows that while the uncertainties are well under control, even  $\mathcal{O}(\alpha^4)$  contributions do need to be included, given that the HVP contributions at NNLO are at the same level as  $\Delta a_\mu^{\text{exp}}[\text{E989}]$ . This surprising finding in Ref. [13] can be understood from enhancements that trace back to both large logarithms  $\log(m_\mu/m_e)$  from electron loops and large numerical prefactors, as, e.g., expected from leptonic light-by-light topologies. The former also arises for NLO corrections to HLBL scattering, but in this case the corresponding enhancement does not counteract the suppression in  $\alpha$  to the same extent [28].

In this Letter, we address the remaining class of  $\mathcal{O}(\alpha^4)$  hadronic corrections, so-called double-bubble topologies shown in Fig. 1. These contributions are subtle, in that care is required to avoid double counting with contributions that already enter LO HVP, given that purely hadronic cuts (and, possibly, to some extent mixed hadronic and leptonic cuts) are included in the measured  $e^+e^- \rightarrow$  hadrons cross section. (We concentrate on the HVP determination from

FIG. 1. Left: double-bubble topology in QED, for outer lepton  $\ell_1$  and inner lepton  $\ell_2$ . Right: example for a hadronic manifestation of the same topology with quarks in the outer loop and lepton  $\ell$  in the inner loop. The opposite case (lepton outer loop, hadrons inner loop) is irrelevant numerically, see main text. Similar diagrams with innerbubble insertions on the same side of the outer loop are not shown, nor are additional diagrams in scalar QED.

$e^+e^-$  data here. In lattice QCD, such topologies would require higher-order QED contributions.) Numerically, potentially relevant effects are again expected from electron loops, and the subtleties in the definition of the LO HVP contribution further motivate a careful study of the different cuts to ensure that no sizable effects are overlooked. To this end, we first analyze the virtual (two-particle cut) and real (four-particle cut) contributions in QED, following the methods developed in the context of higher-order corrections to heavy-quark production [58–66], and then generalize the results to scalar QED to estimate the corrections originating from the leading hadronic channel  $e^+e^- \rightarrow \pi^+\pi^-$ . This strategy allows us to calculate complicated four-loop contributions in an efficient and transparent manner, since the spectral functions that emerge at intermediate steps directly correspond to physical cross sections.

*QED.*—The vacuum polarization (VP) diagrams in Fig. 1 produce a contribution to  $a_\mu$  via

$$a_\mu = \frac{\alpha}{\pi} \int_0^1 dx (1-x) \bar{\Pi}(s_x), \quad s_x = -\frac{x^2 m_\mu^2}{1-x}, \quad (4)$$

where  $\bar{\Pi}(s)$  is the renormalized scalar VP function in the sign convention that the fine-structure constant runs as  $\alpha(s) = \alpha(0)/[1 - \bar{\Pi}(s)]$ . We will evaluate Eq. (4) via the dispersion relation

$$\bar{\Pi}(s) = \frac{s}{\pi} \int_{s_{\text{thr}}}^{\infty} ds' \frac{\text{Im} \Pi(s')}{s'(s' - s)}, \quad (5)$$

since  $\text{Im} \Pi(s)$  can be directly related to the cuts of the diagrams. To be explicit, one has the relation

$$\text{Im} \Pi(s) = -\frac{\alpha}{3} R(s), \quad (6)$$

where the  $R$  ratio is defined as

TABLE I. Contributions to  $a_\mu$  in units of  $(\alpha/\pi)^4 \simeq 2.9 \times 10^{-11}$ . The upper panel refers to the QED diagrams (left in Fig. 1), the last line to an estimate of the  $\pi^+\pi^-$  contribution in scalar QED (right in Fig. 1). The virtual and real parts correspond to the two- and four-particle cuts, respectively.

	Virtual	Real	Total	Refs. [2,68]
$\ell_1 = \ell_2 = e$	-3.56	5.00	1.44	1.4407623(330)
$\ell_1 = \mu, \ell_2 = e$	-0.11	0.27	0.16	0.1619701(214)
$\ell_1 = e, \ell_2 = \mu$	0.02	0.002	0.02	0.0215813(40)
$\ell = e$	-0.13	0.25	0.12	

$$R(s) = \frac{\sigma(e^+e^- \rightarrow \text{hadrons})}{\sigma_0}, \quad \sigma_0 = \frac{4\pi\alpha^2}{3s}. \quad (7)$$

Of course, the same formula also works for leptonic final states, so that the left diagram in Fig. 1 can be reconstructed from the  $\ell_1^+ \ell_1^-$  cut, starting at  $s_{\text{thr}} = 4m_{\ell_1}^2$ , and the  $\ell_1^+ \ell_1^- \ell_2^+ \ell_2^-$  cut, starting at  $s_{\text{thr}} = (2m_{\ell_1} + 2m_{\ell_2})^2$ . As a first step, we work out the results for the cases  $\{\ell_1 \ell_2\} = \{ee, \mu e, e\mu\}$ , since the separation into the two cuts, referred to as virtual and real contributions, respectively, will allow us to draw first conclusions on the hadronic case.

To this end, we introduce the notation

$$R_{\ell_1 \ell_2}^{(2)}(s) = \left(\frac{\alpha}{\pi}\right)^2 [\rho_{\ell_1 \ell_2}^V(s) + \rho_{\ell_1 \ell_2}^R(s)] \quad (8)$$

for the two-loop contribution to  $R(s)$  and separate the scaling in  $\alpha/\pi$  to obtain the spectral functions  $\rho_{\ell_1 \ell_2}^{V,R}$  for the virtual and real parts.

The virtual spectral function can be calculated by yet another dispersion relation,

$$\begin{aligned} \rho_{\ell_1 \ell_2}^V(s) &= (3 - \beta_1^2) \beta_1 \text{Re} F_1^{\ell_1 \ell_2}(s) + 3\beta_1 \text{Re} F_2^{\ell_1 \ell_2}(s), \\ F_i^{\ell_1 \ell_2}(s) &= \frac{1}{3} \int_{4m_\ell^2}^{\infty} \frac{d\lambda^2}{\lambda^2} F_i^{\ell_1 \lambda}(s, \lambda^2) R_{\ell_2}(\lambda^2), \end{aligned} \quad (9)$$

where

$$R_\ell(s) = \sqrt{1 - \frac{4m_\ell^2}{s}} \left(1 + \frac{2m_\ell^2}{s}\right) \quad (10)$$

is the spectral function for the inner lepton  $\ell_2$  and we wrote  $m_i = m_{\ell_i}$  as well as  $\beta_i = \sqrt{1 - 4m_i^2/s}$ . The  $F_i^{\ell_1 \lambda}(s, \lambda^2)$  are the one-loop QED Dirac and Pauli form factors, but calculated for a finite photon mass  $\lambda$  [62,66], see [67] for the explicit expressions. The resulting integral representation (9) works well for  $\ell_1 = \mu$ , leading to the result shown in Table I. For  $\ell_1 = \ell_2 = e$  one can use the analytic result [58,59], reproduced in [67], while for  $\ell_1 = e, \ell_2 = \mu$  in most of the integration range in Eq. (5) the

approximation  $m_1 = 0$  is sufficient. The exception is the region very close to threshold, where a double expansion in  $\beta_1$  and  $m_1^2/\lambda^2$  should be used instead [67]. Finally, the known real spectral function from the four-particle cut is also given in [67].

The sum of the real and virtual contributions reproduces the total results from Refs. [2,68], see Table I. (Related work on the mass-dependent  $\mathcal{O}(\alpha^4)$  QED contributions can be found in Refs. [69–74].) We see that by far the dominant contribution arises from  $\ell_1 = \ell_2 = e$ , as expected given the additional light loop compared to the other two cases. Moreover, we observe that (i) the configuration with an outer electron and inner muon comes out much smaller than the opposite case and (ii) the cancellation of the leading logarithms is most visible for  $\ell_1 = \ell_2 = e$ , with a milder effect already for  $\ell_1 = \mu, \ell_2 = e$ .

Since the muon mass is similar to the hadronic scales, e.g., close to the mass of the pion, these observations provide some first insights for the corresponding diagrams with hadronic degrees of freedom. First, we can ignore the case of an outer electron and inner hadronic loop, since the muon example shows that this configuration contributes only  $\lesssim 10^{-12}$  to  $a_\mu$ . Second, virtual corrections will be included in the  $e^+e^- \rightarrow$  hadrons data in LO HVP, unless removed by hand through the application of higher-order radiative corrections or in Monte Carlo simulations. This implies that the only potentially missing effect concerns the real radiation of an  $e^+e^-$  pair together with hadronic states. In the muon case, this effect amounts to  $\Delta a_\mu \simeq 0.8 \times 10^{-11}$ , which would be negligible for the time being. To corroborate this estimate, we consider a  $\pi^+\pi^-$  loop in scalar QED,

as a realistic example of the hadronic realization of a quark loop, see right diagram in Fig. 1.

*Scalar QED.*—To estimate the potentially missing hadronic contributions more quantitatively, we consider the  $e^+e^- \rightarrow \pi^+\pi^-$  cross section parametrized via the pion vector form factor  $F_\pi^V(s)$ ,

$$\sigma(e^+e^- \rightarrow \pi^+\pi^-) = \frac{\pi\alpha^2}{3s} \beta_\pi^3 |F_\pi^V(s)|^2, \quad (11)$$

with  $\beta_\pi = \sqrt{1 - 4M_\pi^2/s}$ , and evaluate the virtual and real corrections in scalar QED. This strategy is analogous to the calculation of  $\pi\pi\gamma$  radiative corrections [75–78] and captures the infrared enhanced effects, for which the pion can be approximated as a pointlike particle.

The calculation of the virtual contribution proceeds in analogy to Eq. (9),

$$\begin{aligned} \rho_{\pi\ell}^V(s) &= \frac{1}{2} \beta_\pi^3 |F_\pi^V(s)|^2 \text{Re} F^{\pi\ell}(s), \\ F^{\pi\ell}(s) &= \frac{1}{3} \int_{4m_\ell^2}^\infty \frac{d\lambda^2}{\lambda^2} F^{\pi\lambda}(s, \lambda^2) R_\ell(\lambda^2), \end{aligned} \quad (12)$$

where the form factor  $F^{\pi\lambda}(s, \lambda^2)$  fulfills the dispersion relation

$$F^{\pi\lambda}(s, \lambda^2) = \frac{s}{\pi} \int_{4M_\pi^2}^\infty ds' \frac{\text{Im} F^{\pi\lambda}(s', \lambda^2)}{s'(s' - s)}. \quad (13)$$

From the explicit scalar QED calculation we obtain the compact analytic expression

$$\begin{aligned} F^{\pi\lambda}(s, \lambda^2) &= -\frac{1}{4\beta} \left[ 1 + \beta^2 + \frac{2 + \beta^2 - 3\beta^4}{4\beta^2} l + \frac{(1 - \beta^2)^2}{8\beta^2} l^2 \right] \psi(p, l) - \left[ \frac{1}{2\beta^2} + \frac{1 + \beta^2}{8\beta^2} l - \frac{1}{4} \right] \phi(l) \\ &\quad - \frac{1}{16\beta^2} \left[ 1 + \beta^2 + \frac{(1 - \beta^2)^2}{2\beta} \log p \right] l^2 \log l - \frac{1}{16\beta^2} \left[ 4 - 6\beta^2 + \frac{2 + \beta^2 - 3\beta^4}{\beta} \log p \right] l \log l - \frac{(1 - \beta^2)^2 \log^2 p}{64\beta^3} l^2 \\ &\quad + \frac{1}{4} \left[ 1 - \frac{1 - \beta^2}{8\beta^3} \log p [4\beta^2 + (2 + 3\beta^2) \log p] \right] l - \frac{1}{2} \left[ 1 + \frac{1 + \beta^2}{2\beta} \log p \right] \log l - \frac{\log p}{8\beta} (1 + \beta^2)(4 + \log p) - 1 \\ &\quad + i\pi \left\{ -\frac{1}{2\beta} \left[ 1 + \beta^2 + \frac{1 - \beta^2}{4} l \right] + \frac{1}{4\beta} \left[ 1 + \beta^2 + \frac{2 + \beta^2 - 3\beta^4}{4\beta^2} l + \frac{(1 - \beta^2)^2}{8\beta^2} l^2 \right] \log \left[ 1 + \frac{(1 - p)^2}{lp} \right] \right\}, \end{aligned} \quad (14)$$

where  $\beta = \beta_\pi$ ,  $p = [(1 - \beta)/(1 + \beta)]$ ,  $l = \lambda^2/M_\pi^2$ , and

$$\begin{aligned} \phi(l) &= \begin{cases} \frac{1}{2} \sqrt{l^2 - 4l} \log \frac{l - \sqrt{l^2 - 4l}}{l + \sqrt{l^2 - 4l}} & \text{for } l > 4, \\ \sqrt{4l - l^2} \arctan \frac{\sqrt{4l - l^2}}{l} & \text{for } 0 < l < 4, \end{cases} \\ \psi(p, l) &= \frac{1}{2} \log^2 \left( \frac{1}{2} [l - 2 + \sqrt{l^2 - 4l}] \right) + \text{Li}_2 \left( 1 + \frac{p}{2} [-2 + l + \sqrt{l^2 - 4l}] \right) + \text{Li}_2 \left( 1 + \frac{p}{2} [-2 + l - \sqrt{l^2 - 4l}] \right) \\ &\quad + \begin{cases} -\frac{\pi^2}{2} + i\pi \log[(1 - p)^2 + pl] & \text{for } l > 4, \\ -\frac{3}{2} \pi^2 + 4\pi \arctan \frac{\sqrt{4l - l^2}}{l} + 2\pi \arctan \frac{2p + l - 2}{\sqrt{4l - l^2}} & \text{for } 0 < l < 4. \end{cases} \end{aligned} \quad (15)$$

Similarly, real radiation from the scalar QED subprocess leads to the spectral function

$$\rho_{\pi\ell}^R(s) = \frac{4}{3} |F_\pi^V(s)|^2 \int_{y_-}^{y_+} dy \int_{z_-}^{z_+} \frac{dz}{z} \left(1 + \frac{2m_\ell^2}{sz}\right) \sqrt{1 - \frac{4m_\ell^2}{sz}} \left[ \sqrt{1 - \frac{4M_\pi^2}{sy}} \lambda^{1/2}(1, y, z) \left( \frac{1}{8} + \frac{(4M_\pi^2 - 1)(4M_\pi^2 - z)}{32[z + \frac{M_\pi^2}{sy} \lambda(1, y, z)]} \right) \right. \\ \left. + \frac{\frac{16M_\pi^4}{s^2} - \frac{4M_\pi^2}{s} (2y + z + 1) + 2y(z + 1) + z}{16(y - z - 1)} \log \frac{1 - y + z - \sqrt{1 - \frac{4M_\pi^2}{sy}} \lambda^{1/2}(1, y, z)}{1 - y + z + \sqrt{1 - \frac{4M_\pi^2}{sy}} \lambda^{1/2}(1, y, z)} \right], \quad (16)$$

where  $\lambda(x, y, z) = x^2 + y^2 + z^2 - 2(xy + xz + yz)$  and

$$y_- = \frac{4M_\pi^2}{s}, \quad y_+ = \left(1 - \frac{2m_\ell}{\sqrt{s}}\right)^2, \\ z_- = \frac{4m_\ell^2}{s}, \quad z_+ = (1 - \sqrt{y})^2. \quad (17)$$

Both  $F^{\pi\lambda}(s, \lambda^2)$  and  $\rho_{\pi\ell}^R(s)$  are new results.

The numerical evaluation gives the result in the last line of Table I, supporting the conclusions already indicated by the muon example: again, the contribution from the real radiation of  $e^+e^-$  pairs together with final-state  $\pi^+\pi^-$  corresponds to an effect in  $a_\mu$  of less than  $1 \times 10^{-11}$ . We stress that, while the muon loop is expected to produce results similar to hadronic degrees of freedom given the scales involved, the extent to which the effects in  $a_\mu$  agree is largely coincidental. As shown in Fig. 2, the fermionic spectral functions tend to be larger near threshold (due to the  $P$ -wave suppression of the  $\pi^+\pi^-$  channel) and for large  $s$  (where  $F_\pi^V \simeq 1/s$  leads to a suppression), which is then compensated by the  $\rho(770)$  peak at intermediate energies.

FIG. 2. Spectral functions for an inner electron and an outer muon or pion. The figure illustrates how the larger fermionic spectral functions close to threshold and for large  $s$  are compensated by the  $\rho(770)$  peak in between.

*Conclusions.*—In this Letter we addressed a missing class of hadronic corrections to the anomalous magnetic moment of the muon at  $\mathcal{O}(\alpha^4)$ , represented by the double-bubble topologies shown in Fig. 1. As a first step we reproduced the QED configurations involving electron loops by means of the two- and four-particle cuts of these diagrams, and showed that indeed the known results are recovered when adding the virtual and real contributions. In particular, configurations in which the inner loop does not correspond to an electron prove negligible.

Since virtual corrections should be included in the measured  $e^+e^- \rightarrow$  hadrons cross section, we concluded that the only potentially missed contribution could originate from hadronic final states accompanied by  $e^+e^-$  pair emission. To estimate this effect, we argued that the case with an outer muon should provide a first indication, and then calculated the analog in scalar QED for a charged-pion loop. Both results are remarkably close, albeit to a large extent by coincidence, see Fig. 2, and translate to an effect in  $a_\mu$  of  $\lesssim 1 \times 10^{-11}$ . One would thus need a significant enhancement due to experimental cuts or misidentification of  $e^+e^-$  pairs to produce a relevant effect. It might be interesting to verify in experimental analyses that indeed no enhanced effects from  $e^+e^-$  radiation can occur, but absent such a scenario we conclude that this class of mixed leptonic and hadronic corrections is negligible at the level required for the final precision of the Fermilab  $g-2$  experiment.

We thank Makiko Nio for providing the flavor breakdown of the results from Ref. [2], and acknowledge valuable discussions at the workshop [79]. Financial support by the SNSF under Project No. PCEFP2\_181117 (M. H.) and the STFC Consolidated Grant ST/T000988/1 (T. T.) is gratefully acknowledged.
