37

38 **Abstract** (maximum 300 words) – 296

39 **Background** Little is known about what factors are important to older adults when
40 deciding whether to agree with a recommendation to deprescribe.

41 **Objective** To explore the extent to which medication type and rationale for potential
42 discontinuation influence older adults' acceptance of deprescribing.

43 **Design** Cross-sectional 2 (drug: lansoprazole- treat indigestion; simvastatin- prevent
44 cardiovascular disease) by 3 (deprescribing rationale: lack of benefit; potential for harm;
45 both) experimental design.

46 **Participants** Online panelists aged ≥ 65 years from Australia, Netherlands, United
47 Kingdom, and United States

48 **Interventions** Participants were presented with a hypothetical patient experiencing
49 polypharmacy whose PCP discussed stopping a medication. We randomized
50 participants to receive one of six vignettes.

51 **Main Measures** We measured agreement with deprescribing (6-point Likert scale,
52 'Strongly disagree (1)' and 'Strongly agree (6)') for the hypothetical patient as the
53 primary outcome. We also measured participants' personality traits, perceptions of risk
54 and uncertainty, and attitudes towards polypharmacy and deprescribing.

55 **Key Results** Among 5,311 participants (93.3% completion rate), the mean (M)
56 agreement with deprescribing for the hypothetical patient was 4.71 (95% confidence
57 interval (CI): 4.67,4.75). Participants reported higher agreement with stopping
58 lansoprazole (n=2,656) (M=4.90, 95% CI: 4.85,4.95) compared to simvastatin (n=2,655)

59 (M=4.53, 95% CI: 4.47,4.58), $P<.001$. Participants who received the combination
60 rationale (n=1,786) reported higher agreement with deprescribing (M=4.83, 95% CI:
61 4.76,4.89) compared to those who received the rationales on lack of benefit (n=1,755)
62 (M=4.66, 95% CI: 4.60,4.73) or potential for harm (n=1,770) (M=4.65, 95% CI
63 4.58,4.72). In adjusted regression analyses (n=5,062), participants with a higher desire
64 to engage in health promotion behaviors (b=0.08, 95% CI 0.02,0.13) or need for
65 certainty (b=0.12, 95% CI 0.04,0.20) reported higher agreement with deprescribing.
66 **Conclusions** Older adults across four countries were accepting of deprescribing in the
67 setting of polypharmacy. The medication type and rationale for discontinuation were
68 important factors in the decision-making process.

69

70 **Introduction**

71 The use of chronic medications in older adults can have diminishing benefit and
72 become potentially unsafe over time due to factors including physiological changes
73 associated with aging; the accumulation of multiple chronic health conditions leading to
74 more medications; and drug-drug and drug-disease interactions.^{1,2} Globally, up to 50%
75 of adults aged 65 years and above take one or more inappropriate medications, which
76 has been associated with functional decline, reduced quality of life, and increased
77 health care costs.³

78

79 One important approach that may reduce inappropriate or unnecessary medication use
80 among older adults is deprescribing, the process of tapering or stopping medications
81 lacking benefit or potentially causing harm.⁴ Existing efforts have mostly focused on
82 providing guidance to clinicians about the deprescribing process but have less often
83 focused on patients.⁵⁻¹⁰ Involving the patient in deprescribing decisions is critical to
84 ensuring that the plan aligns with the patient's preferences and goals.¹¹⁻¹⁵

85

86 Existing literature on patients' perspectives on deprescribing shows mixed results.^{16,17} Many
87 older adults have expressed interest in stopping unnecessary medications while at the same
88 time preferring to continue their current medications¹⁸, citing concerns about what will occur
89 during and after the deprescribing process (e.g. withdrawal effects, recurrence of
90 symptoms).^{11,17-23} Better understanding of what factors influence older adults in
91 deprescribing decisions is critical. We sought to address this knowledge gap using a

92 vignette-based experiment. We explored the extent to which the type of medication (i.e.
93 preventive vs. symptomatic treatment) and rationale for potential discontinuation (i.e.
94 lack of benefit, potential for harm, or both) influenced older adults' agreement with a
95 recommendation from the primary care physician to deprescribe a medication for a
96 hypothetical patient.

97

98 **Methods**

99 We conducted a vignette-based online experiment using hypothetical vignettes with
100 older adults recruited from Australia, United Kingdom (UK), United States (US), and the
101 Netherlands. We chose these countries because they have markedly different
102 healthcare systems and our research team have experience with the healthcare
103 systems within these countries. This study was deemed exempt by the University of
104 Michigan Institutional Review Board (IRB) and registered as a clinical trial at
105 Clinicaltrials.gov Identifier: NCT04676282.

106

107 *Study Design and Sample*

108 Participants were demographically diverse samples of older adults aged 65 years and
109 above recruited through a panel of Internet users administered by Qualtrics Research
110 Panels (Provo, UT) from December 2020 through March 2021.²⁴ Qualtrics used various
111 opt-in methods to assemble their panel. For our project, a random subset of eligible
112 panelists were invited to participate according to our study's pre-specified sample size
113 and demographic distributions. We focused our power calculation on how three different

114 rationales for deprescribing would impact agreement with a recommendation for
115 deprescribing from a physician. We determined that a sample size of 1,200 for each
116 country would allow us to detect a 10% difference in level of agreement with a
117 dichotomous primary outcome measure with power=0.80 and $\alpha=0.05$ for a variable with
118 3 levels. We included quotas to ensure equal numbers of participants from each country
119 and 50% of participants from each country would be female. For the US participants, we
120 established quotas based on race and ethnicity that aligned with the national data (18%
121 Hispanic, 15% African American, 5% Asian, 62% White/Other race/ethnicity). The
122 sampling algorithm continued to invite panelists to complete the survey until all quotas
123 were achieved. Strategies such as checking IP addresses, digital fingerprint technology,
124 and deduplication technology were used to prevent multiple responses by one
125 participant. To avoid self-selection bias, survey invitations did not include the study
126 topic. The survey was administered in English for the US, UK, and Australia, and
127 translated and administered in Dutch for the Netherlands.

128

129 All data were collected anonymously using Qualtrics software (Provo, UT). Participants
130 were compensated based on the conditions of their panel agreement.

131

132 *Intervention*

133

134 We created a vignette about “Mrs. EF”, a 76-year-old who uses 11 medications to
135 manage her multiple health conditions based on previous work of Todd *et al.* (Text

136 box).^{16,18} We sought to bring Mrs. EF to life by including details about her medical
137 history, social history, and general attitudes and beliefs about her doctor and
138 medications.²⁰ By including her medication list as a figure in the survey, we aimed to
139 better communicate the potential burden of her current medication regimen. After
140 displaying this information, we asked participants to imagine that Mrs. EF was going to
141 her primary care provider (PCP) for a routine visit.

142

143 The vignette-based online experiment examined the extent to which the type of
144 medication (i.e. preventive vs. symptomatic treatment) and rationale for potential
145 discontinuation (i.e. lack of benefit, potential for harm, or both) influenced participants'
146 agreement with a recommendation from Ms. EF's PCP for her to deprescribe a
147 medication. We programmed the survey to randomize participants to receive one of six
148 vignettes using a 2 (lansoprazole, to treat indigestion; simvastatin, to prevent heart
149 disease and stroke) by 3 (lack of benefit; potential for harm; or combination of both)
150 experimental design (Figure 1). Randomization was set such that each vignette was
151 displayed an equal number of times. The rationale for selecting these medications in our
152 vignette was both statins (HMG-CoA reductase inhibitors) and proton pump inhibitors
153 are frequent targets of deprescribing.²⁵⁻²⁹

154

155 The survey was refined based on feedback from patient and public engagement groups.
156 We (JJ and a bilingual medical student) identified existing Dutch versions of validated
157 scales and translated the rest of the survey into Dutch. We made minor modifications to

158 the scenario wording to align with the context of the different countries (e.g., changing
159 PCP to General Practitioner for participants outside the US). We piloted the survey with
160 50 participants per country through Qualtrics and made revisions to improve survey
161 length.

162

163 *Outcome measures*

164 Primary outcome

165 1. *Agreement with deprescribing recommendation*: The participants' attitude
166 towards deprescribing as measured by the extent of agreement with the
167 statement, 'I think that Mrs. EF should follow the doctor's recommendation and
168 stop taking [medication],' on a 6-point Likert scale with 'Strongly disagree (1)' and
169 'Strongly agree (6)' as the scale anchors.

170 Covariates

171 1. *Personality traits*

172 a. *Preferences for more or less medical care*: The single item Medical
173 Maximizer-Minimizer measure (MM1) measured preferences for seeking
174 medical care, ranging from 'I strongly lean towards waiting and seeing (1)'
175 to 'I strongly lean towards taking action (6)'.³⁰

176 b. *Beliefs about medicines*: The 18-item Beliefs about Medicines
177 Questionnaire (BMQ) measured levels of agreement with medication use
178 in general, the necessity of medications, and concerns about medications

179 on a 5-point scale, with 'Strongly disagree (1)' to 'Strongly agree (5)' as
180 the scale anchors.^{31,32}

181 c. *Health promotion/prevention*: The 12-item Health Regulatory Focus Scale
182 (HRFS) measured desire to engage in actions to *promote health* or
183 *prevent poor health*, with 'Not at all (1)' to 'A great extent (7)' as the scale
184 anchors.³³

185 d. *Attitude towards uncertainty*: The 8-item Attitude towards Uncertainty
186 scale measured individuals' comfort level regarding uncertainty, with
187 'Strongly disagree (1)' and 'Strongly agree (5)' as the scale anchors.³⁴

188 2. *Health literacy*: Participants' confidence filling out medical forms was measured
189 using a single item with responses ranging from 'Not at all (1)' to 'Excellent
190 (5)'.^{39,40}

191 3. *Subjective health status*: Participants' perceptions of their health as measured by
192 their response to the question 'In general, how would you rate your health
193 today?' with responses ranging from 'Poor (1)' to "Excellent (5)".³⁸

194 4. *Personal experience with medication*: Participants' self-report of taking a
195 medication in the same therapeutic class as the medication presented in the
196 scenario (i.e. statin or proton pump inhibitor) with responses of 'Current,'
197 'Previous use,' or 'Never used'.

198 5. *Risk perceptions*: We adapted the 6-item Tripartite Model of Risk Perception
199 (TRIRISK) scale that measures Deliberative, Affective, and Experiential risk
200 perceptions with questions such as, "How likely do you think it is that Mrs. EF's

201 heart health will worsen at some point in the future with simvastatin?” with ‘Very
202 unlikely (1)’ and ‘Very likely (7)’ as the scale anchors.³⁶

203 6. *Attitudes towards medications*

204 a. *Stopping a medication (positive, beneficial, not harmful)*: These three
205 adapted single item measures on a 10-point scale: ‘I think that Mrs. EF
206 stopping [medication] would be...’ ‘Very positive (1)’ to ‘Very negative
207 (10)’, ‘Very beneficial (1)’ to ‘Not beneficial (10),’ ‘Not harmful (1)’ to ‘Very
208 harmful (10)’ as the scale anchors.^{35,36}

209 b. *Number of medications*: Adapted single item measure: ‘Mrs. EF takes 11
210 medicines. How positive or negative do you feel towards the number of
211 medicines that Mrs. EF takes?’ with ‘Very negative (1)’ and ‘Very positive
212 (10)’ as the scale anchors.³⁷

213

214 *Demographics and medication use*

215 Country, age, gender, and education were measured. Number of medications taken
216 (prescription, non-prescription and or dietary supplements) and amount of support
217 needed for managing their medications as collected. Participants were also asked to
218 “thoughtfully provide your best answers to each question” and individuals who selected
219 “I will not provide my best answers” or “I can’t promise either way” were excluded from
220 the study.

221

222 *Statistical Analysis*

223 We calculated descriptive statistics and conducted independent samples t-tests and
224 ANOVAs to compare group means. We used ordered logistic regression to examine
225 factors associated with agreement with stopping medications using the 6-point Likert
226 scale and included experimental factors (drug in scenario, rationale for stopping
227 medication), personality traits, participant characteristics (i.e. county of residence, age,
228 gender, education, health literacy, health status, and personal use of the medication),
229 risk perceptions, attitudes towards deprescribing, and positive attitudes towards
230 polypharmacy. We used a statistical significance level of $P < .017$ to account for the
231 number of similar analyses ($P < 0.05$ divided by 3). Case-wise deletion was used for
232 missing data for the ordered logistic regression analysis. All analyses were conducted
233 with Stata, version Stata SE 16.0 (StataCorp). We reported our study according to the
234 Strengthening the Reporting of Observational Studies in Epidemiology (STROBE)
235 checklist.⁴¹

236

237

238

239 **Results**

240 A total of 5,693 individuals started the survey. We excluded participants who were
241 younger than 65 years or did not reside in a participating country ($n=301$) and 81
242 participants who did not agree to give high quality answers. The final analytical sample
243 comprised 5,311 participants (93.3% completion rate).

244

245 The mean age of participants was 71.4 years (SD 4.9 years). Most participants reported
246 earning less than a Bachelor's degree (65.2%), being in good health (43.0%), and being
247 extremely confident filling out medical forms (44.2%). Participants reported taking an
248 average of 7.0 medications (SD 10.9).

249

250 The mean (M) level of agreement with stopping the medication was 4.71 (on a 6-point
251 Likert scale, 95% CI: 4.67,4.75), but participants reported higher agreement with
252 stopping lansoprazole (M=4.90, 95% CI: 4.85,4.95) compared to simvastatin (M=4.53,
253 95% CI: 4.47,4.58), $P<.001$. Participants who received the combination rationale
254 reported higher agreement with stopping the medication (M=4.83, 95% CI: 4.76,4.89)
255 compared to those who received the rationales only related to lack of benefit (M=4.66,
256 CI: 4.60,4.73) or potential for harm (M=4.65, 95% CI 4.58,4.72). Willingness to stop
257 lansoprazole remained higher than simvastatin ($b=0.24$, 95% CI 0.12,0.35) when
258 controlling for covariates (Table 3).

259

260 Participants who were given the deprescribing rationale about the medication's lack of
261 benefit in combination with a potential for harm had higher agreement that Mrs. EF
262 should follow her PCP's recommendation to deprescribe than with either rationale alone
263 (Table 2), $F(2, 5,295)=8.93$, $P<0.001$. However, when controlling for covariates,
264 participants had higher agreement with the recommendation to deprescribe when the
265 potential for harm was provided for either medication ($b=0.16$, 95% CI 0.02,0.29), as
266 opposed to the lack of benefit or a combination of lack of benefit and potential for harm.

267

268 We found that participants across all four countries reported high level of agreement
269 with recommendation for deprescribing (Table 2). In unadjusted analyses, participants
270 in Australia and the US were more willing to agree with the recommendation for
271 deprescribing (Appendix 2a and 2b), $F(3,5294)=10.24$, $P<0.001$. However, participants
272 in the UK reported increased agreement with stopping the medications (Table 3) when
273 controlling for covariates.

274
275 Participants frequently reported personal experience currently or previously taking a
276 statin (53.2%) or proton pump inhibitor (40.5%). In adjusted analyses, individuals who
277 reported previously taking the therapeutic class of medication presented in the scenario
278 reported higher agreement with deprescribing compared with those currently taking the
279 medication ($b=0.23$, 95% CI 0.04,0.42). There was no difference in agreement with
280 deprescribing among participants who currently or never took the medication.

281
282 There were several attitudes towards medications and risk perceptions that were
283 predictive of less agreement with stopping the medication (Table 3). These included
284 feeling that stopping a medication would be negative ($b=-0.35$, 95% CI -0.39,-0.30)), not
285 beneficial ($b=-0.41$, 95% CI -0.45,-0.36), or harmful ($b=-0.10$, 95% CI -0.13,-0.07);
286 positive perceptions of taking 11 medications daily ($b=-0.04$, 95% CI -0.07,-0.01) or
287 feeling anxious or worried that Mrs. EF's health would worsen in the future without the
288 medication ($b=-0.23$, 95% CI -0.30,-0.16) (Affective risk perceptions).

289

290 Finally, for the personality traits, individuals with a higher desire to engage in health
291 promotion behaviors ($b=0.08$, 95% CI 0.02,0.13) or a higher need for certainty ($b=0.12$,
292 95% CI 0.04,0.20) reported higher agreement with stopping the medication. There were
293 no statistically significant associations between agreement with deprescribing and
294 medical maximizing, beliefs about medicines questionnaire, and the desire to engage in
295 actions to prevent poor health.

296

297 **Discussion**

298 Deprescribing of inappropriate medications is increasingly recognized as an important
299 strategy for optimizing medication use among older adults.⁴² However, several
300 systematic reviews have shown there is resistance to deprescribing in clinical practice
301 from both patients and clinicians.^{17,43,44} Our findings, from the largest international
302 deprescribing survey to date, show that older adults were significantly more accepting of
303 a recommendation to stop a medication to treat a symptom that can be self-monitored
304 compared to a medication to prevent future health problems. This may have been due
305 to the heightened perceived importance of the medication itself (a medication for the
306 heart), concerns about having a cardiovascular event if the medication was stopped,
307 and the lack of ability to monitor the impact of a preventive medication.

308

309 In contrast, Vordenberg et al. previously reported that adults 65 years and older in the
310 US reported similar rates of concern about stopping medications that differed based on

311 risk, regulatory status, and indication for discontinuation.²⁰ However, the study
312 presented one medication at a time without patient-related information.²⁰

313

314 When discussing deprescribing, a clinician may focus on the balance of benefits and
315 harms, quality of life, diminishing returns, and uncertainty of evidence for specific
316 medications.⁴⁵ However, it is not feasible to include all of these topics in a brief medical
317 visit. A recent discrete choice experiment study found that Danish general practitioners
318 prefer a brief, as opposed to none or detailed, discussion with patients about statin
319 deprescribing.⁴⁶ In systematic reviews, Hoffmann *et al.* identified that patients and
320 clinicians inaccurately perceive the potential benefits of treatments (overestimate) and
321 the harms (underestimate) which could influence deprescribing.^{47,48} It has been posited
322 that the benefit of medicines is often taken for granted so informing individuals that their
323 medicine lacks benefit may not resonate or be convincing enough to counteract the
324 assumption that medicines are beneficial.³¹ Interestingly, our findings indicate that older
325 adults across four diverse countries are more likely to agree with stopping a medication
326 when they are presented with information about the potential harm of the medication.
327 This suggests that if an individual is presented with the potential for harm of a
328 medication, this may challenge strong beliefs about the potential benefits of medicines
329 in general and raise concerns, which could in turn create an opportunity to deprescribe.
330 Our work suggests that PCPs should focus on potential harms when discussing
331 deprescribing recommendations with patients.

332

333

334 Research suggests that a person's experience with deprescribing in the past can
335 influence their attitudes towards deprescribing in the present.⁴⁹ Rozsnyai et al. found
336 that older adults who reported a negative deprescribing experience were less likely to
337 support deprescribing.⁵⁰ In our study, participants who reported previously taking a
338 medication in the same therapeutic class as the medication under consideration for
339 deprescribing in the vignette reported higher agreement with deprescribing Mrs. EF's
340 medication. While we did not collect information about the participants' actual
341 experience stopping the medication or the reason for deprescribing, it appears that it
342 was successful in that they were no longer taking the medication. Integrating
343 deprescribing as part of usual care and increasing older adults' experiences with it could
344 significantly increase deprescribing uptake throughout an individual's life.

345

346 A key strength of our work is that it is the largest deprescribing survey to date and it
347 included a sample of older adults across four countries with different healthcare
348 systems. We used an experimental design which enabled the vignette to be held
349 constant across conditions, allowing the impact on agreement with the PCP's
350 recommendation to deprescribe to be directly attributed to the effect of the
351 manipulations. Furthermore, we adjusted our analysis for a range of important factors
352 using validated scales. In addition, we worked with consumer stakeholder groups to
353 ensure that the scenario represented a realistic and relatable person.

354

355 The primary limitation to this study is that the decisions that people make in a vignette
356 may not align with their real-life decisions. Furthermore, we used lansoprazole to
357 represent symptom control and simvastatin to represent a preventive medication;
358 however, additional work is needed to see if the results would be replicated with other
359 medications. Additional work is needed to understand the influence between specific
360 language used in the intervention on an individual's acceptance of a deprescribing
361 recommendation. While our sample included substantial diversity, we make no claims
362 that it is representative of all older adults in these countries, if only because our
363 participants shared the common characteristic of being willing to participate in survey
364 research using an online platform.

365 **Conclusion**

366 In this study using vignettes, a majority of older adults across four countries agreed with
367 the recommendation by a PCP to deprescribe a medication for someone experiencing
368 polypharmacy. Participants were more inclined to agree with deprescribing a medication
369 for the treatment of a symptom rather than health prevention. Our work suggests that
370 PCPs should focus on potential harms when discussing deprescribing
371 recommendations. Our findings have application in future deprescribing intervention
372 studies or to deprescribing guidelines or algorithms, as we have identified points of
373 discussion about medications that are important to patients and may increase the
374 likelihood of deprescribing.

566 Mrs. EF is a 76-year-old female who has multiple health conditions including:

- 567 • Atrial fibrillation (irregular heartbeat)
- 568 • Chronic obstructive pulmonary disease (chronic breathing problem)
- 569 • Constipation
- 570 • Depression
- 571 • High blood pressure
- 572 • High cholesterol
- 573 • History of blood clots
- 574 • Indigestion (upset stomach)
- 575 • Prevention of brittle bones (osteoporosis)

576 Mrs. EF has regularly seen her primary care provider (PCP) for the past 10 years to help manage her
 577 health. A PCP is a doctor, nurse practitioner, or physician assistant who sees people for common medical
 578 conditions. She trusts her PCP.

579 Over the years, her PCP has prescribed 11 medications. She takes all of the medications according to
 580 the directions (see picture below).

Name	Used For	Morning 	Night 	Only if needed
Atenolol	Lower blood pressure	✓		
Citalopram	Depression	✓		
Hydrochlorothiazide	Lower blood pressure	✓		
Lansoprazole	Indigestion (upset stomach)	✓		
Lisinopril	Lower blood pressure	✓		
Tiotropium	Chronic breathing problem	✓		
Calcium	Prevention of brittle bones (osteoporosis)		✓	
Senna	Constipation		✓	
Simvastatin	Lower cholesterol		✓	
Warfarin	Prevent blood clots		✓	
Albuterol	Shortness of breath from chronic breathing problem			✓

581

582

[page break]

583 **Mrs. EF believes that is a good idea to take medications if they benefit her health, even if the**
584 **benefit is very small. However, Mrs. EF also doesn't really like having to take medications.**

585 She has had a number of problems including feeling tired, having constipation, and occasionally feeling
586 dizzy. She talked with her PCP about this in the past and it was unclear which, if any, medication is
587 causing these problems.

588 Mrs. EF's husband was diagnosed with cancer several years ago and he recently had a stroke. She has
589 been very busy taking care of him which has made it more difficult for her to manage her health
590 conditions through lifestyle changes, such as eating healthy foods and being physically active. **Taking**
591 **care of her husband has made her want to take care of her own health even more than in the past.**

592 [page break]

593 **Mrs. EF is at a routine visit with her PCP today.** The following conversation takes place during the
594 visit:

595 **PCP:** *"I was looking at your list of medication and I would like to talk with you about potentially making a*
596 *change."*

597 **Mrs. EF:** *"What type of change?"*

598 **PCP:** *"I know that you have been taking [simvastatin/lansoprazole] once a day for several years. We*
599 *talked about how this medication would lower your cholesterol and, in turn, help to prevent heart disease*
600 *and strokes."*

601 **Mrs. EF:** *"Yes, I make sure to take [simvastatin/lansoprazole] every day. I never skip a dose because I*
602 *know it is important."*

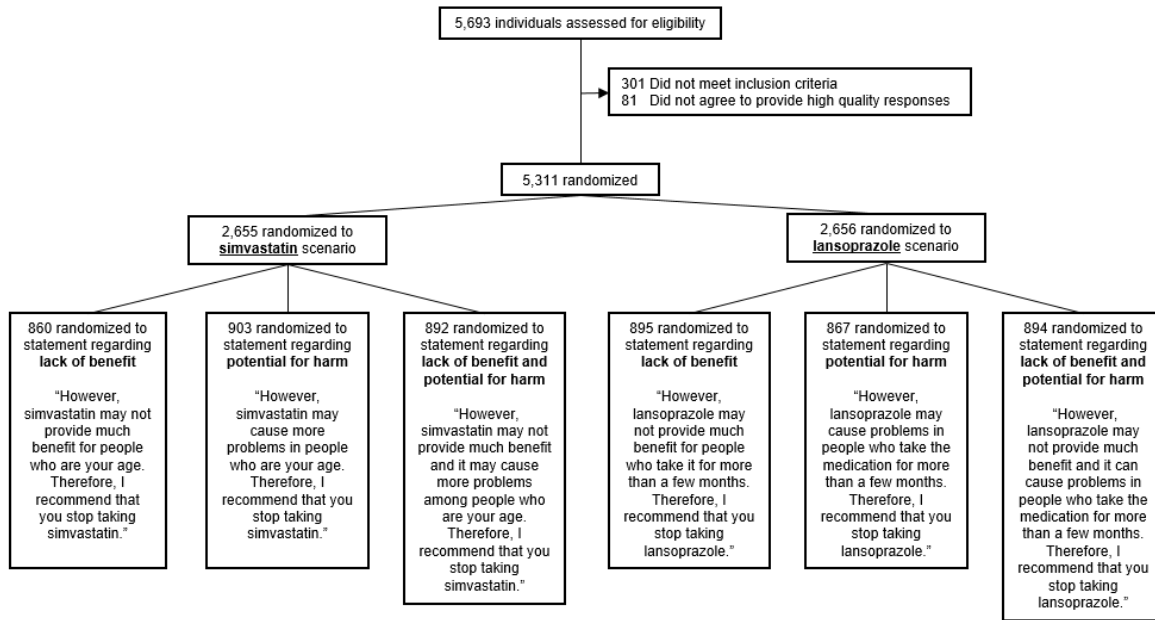

603 **PCP:** *"That's great that you have been taking it every day. I am glad that you have [never had a*
604 *stroke/not been having any indigestion]. However [rationale related to either lack of benefit, potential*
605 *for harm, or a combination of lack of benefit and potential for harm – see Figure 1]"*

606 Based on what you have read so far, please choose how much you agree or disagree with the following
607 statement:

608 **I think that Mrs. EF should follow her PCPs recommendation and stop taking**
609 **[simvastatin/lansoprazole].** (6-point Likert scale; 1=strongly disagree, 6=strongly agree)

Mrs. EF is at a routine visit with her PCP today. The following conversation takes place during the visit:

PCP: "I was looking at your list of medication and I would like to talk with you about potentially making a change."

Mrs. EF: "What type of change?"

PCP: "I know that you have been taking simvastatin once a day for several years. We talked about how this medication would lower your cholesterol and, in turn, help to prevent heart disease and strokes."

Mrs. EF: "Yes, I make sure to take simvastatin every day. I never skip a dose because I know it is important."

PCP: "That's great that you have been taking it every day. I am glad that you have never had a stroke. **However, simvastatin may cause more problems in people who are your age. Therefore, I recommend that you stop taking simvastatin.**"

627

Based on what you have read so far, please choose how much you agree or disagree with the following statement:

I think that Mrs. EF should follow her PCPs recommendation and stop taking simvastatin.

629 * In this example, the Primary Care Provider recommends discontinuation of simvastatin as it may cause
630 harm. This version was displayed to participants in the United States. Participants in Australia and the
631 United Kingdom received the same version except General Practitioner replaced Primary Care Provider.
632 Participants from the Netherlands received a version with the terminology General Practitioner and the
633 survey was administered in Dutch.
