27 Abstract

- **Background:** Long QT syndrome type 2 (LQT2) is caused by pathogenic variants in *KCNH2*.
- 29 LQT2 may manifest as QT prolongation on an ECG and present with arrhythmic
- 30 syncope/seizures, sudden cardiac arrest/death. Oral progestin-based contraceptives may increase
- 31 the risk of LQT2-triggered cardiac events in women. We previously reported on a LQT2 woman
- 32 with recurrent cardiac events temporally related and attributed to the progestin-based

33 contraceptive, medroxyprogesterone acetate ("Depo-Provera", Depo).

34 **Objective:** To evaluate the arrhythmic-risk of Depo in a patient-specific induced pluripotent

- 35 stem cell-derived cardiomyocyte (iPSC-CM) model of LQT2.
- 36 Methods: An iPSC-CM line was generated from a 40-year-old female with p.G1006Afs*49-

37 KCNH2. A CRISPR/Cas9 gene-edited/variant-corrected, isogenic control (IC) iPSC-CM line

38 was generated. FluoVolt was used to measure the action potential duration (APD) following

- 39 treatment with 10 µM Depo. Erratic beating patterns characterized as alternating spike
- 40 amplitudes, alternans, or early after depolarization-like phenomena were assessed using multi-

41 electrode array (MEA) following 10 µM Depo, 1 µM isoproterenol (ISO), or combined Depo +

42 ISO treatment.

- 43 **Results:** Depo treatment shortened the APD-90 of the G1006Afs*49 iPSC-CMs from 394±10
- 44 ms to 303 ± 10 ms (p<0.0001). Combined Depo and ISO treatment increased the percent of
- 45 electrodes displaying erratic beating in G1006Afs*49 iPSC-CMs [baseline 18±5% vs. Depo +
- 46 ISO 54 \pm 5% (p<0.0001)] but not in IC iPSC-CMs [baseline 0 \pm 0% vs. Depo + ISO 10 \pm 3%

47 (p=0.9659)].

48 **Conclusion:** This cell study provides a potential mechanism for the patient's clinically

49 documented Depo-associated episodes of recurrent ventricular fibrillation. This in-vitro data

- 50 should prompt a large-scale clinical assessment of Depo's potential pro-arrhythmic effect in
- 51 women with LQT2.

Journal Prevention

54 INTRODUCTION

Congenital long QT syndrome (LQTS) is an inherited disorder of cardiac repolarization that 55 56 affects an estimated 1 in 2,000 individuals. From a cellular electrophysiology perspective, 57 abnormal cardiac ion channel function increases ventricular action potential duration (APD) and may manifest clinically as a prolonged heart-rate corrected QT interval (QTc) on a 12-lead 58 electrocardiogram.¹ Patients with LQTS are at increased risk for syncope, seizures, and even 59 60 sudden cardiac death particularly following a triggered event associated with exertion, extreme emotion, or auditory stimuli. Three LQTS-causative genes (KCNQ1, KCNH2, and SCN5A) 61 encoding for cardiac ion channels account for the vast majority of genetically proven cases.^{2, 3} 62 While LQTS is typically inherited in an autosomal dominant pattern, environmental 63 modifiers such as sex hormones affect the substrate of males and females with LQTS differently. 64 Female sex hormones such as estrogen and progesterone play complex roles in modulating the 65 ion channels responsible in LQTS pathogenesis. Postpubertal LQTS women are at an increased 66 risk for cardiac events compared to postpubertal men and recent studies indicate an increased 67 risk of cardiac events with use of progestin-only oral contraceptives, particularly in women with 68 LOT2.4,5 69

Previously, we reported the case of a woman diagnosed clinically and genetically with
LQT2 that experienced recurrent LQT2-triggered cardiac events including several ventricular
fibrillation (VF)-terminating therapies from her implantable cardioverter defibrillator (ICD)
while taking medroxyprogesterone acetate (Depo-Provera, Depo), an injectable, synthetic
progestin commonly used as hormonal contraception.⁶ Although endogenous progesterone
shortens the QT interval, the effects of Depo have never been studied.⁷ Herein, we present the

76 first-ever evaluation of Depo in an induced pluripotent stem cell-derived cardiomyocyte (iPSC-

77 CM) model of LQT2 derived from the woman in our original case report.

78 METHODS

79

80 Patient samples

81 Peripheral blood mononuclear cells (PBMCs) were collected at the Mayo Clinic, Rochester, MN

from a 40-year-old female diagnosed with LQT2 and positive for the p.G1006Afs*49-KCNH2

83 pathogenic variant following written informed consent in accordance with Mayo Clinic Internal

84 Review Board (IRB number 09-006465) approved study. To prevent the re-identification of the

85 patient included in this study, individual patient data will not be made available to other

86 researchers. The authors declare that all supporting data are available within the article and its

87 online supplementary files. The research reported in this paper adhered to Helsinki Declaration88 guidelines.

Generation of patient-specific and isogenic control induced pluripotent stem cell derived
 cardiomyocytes

91 Generation of patient-specific induced pluripotent stem cells (iPSC) from PBMCs, creation of

92 CRISPR/Cas9 gene-edited/variant-corrected, isogenic control (IC) iPSCs by Applied StemCell

93 (Milipitas CA), cardiomyocyte differentiation and cardiomyocyte dissociation were performed as

94 described previously.^{8, 9} Standard iPSC and iPSC-derived cardiomyocyte (iPSC-CM) quality

95 control measures including karyotyping, Sanger sequencing variant confirmation, and

96 immunostaining for pluripotent markers (Tra-1-60, SSEA-3, OCT4 and Nanog) were performed

97 as described previously.^{8,9} A list of primers and antibodies used are presented in **Supplemental**

Table 1 and **Supplemental Table 2**. Detailed methods are presented in the **Supplement**.

99 Electrophysiological property and arrhythmia analysis

| 100 | The iPSC-CMs of p.G1006Afs*49-KCNH2 were assessed for their cardiac cellular |
|-----|---|
| 101 | electrophysiologic properties before and after administration of 10 μ M Depo |
| 102 | (medroxyprogesterone acetate). Fluovolt voltage-sensing dye was used for optical action |
| 103 | potential duration (APD) measurements. Multi-electrode array (MEA) was used to measure field |
| 104 | potential durations (FPD), corrected for beating frequency using the Fridericia formula (FPDc), |
| 105 | and for assessing iPSC-CM beating patterns following administration of 10 μ M Depo under both |
| 106 | baseline and 1 μ M isoproterenol (ISO) to mimic adrenergic surge conditions. Each dot in the |
| 107 | MEA results figure represents a technical replicate (one electrode). Erratic beating frequency |
| 108 | was adjudicated manually from electrical tracings after processing with the Comprehensive In |
| 109 | Vitro Proarrhythmia Assay (CiPA) tool (Axion BioSystems) and classified as alternating spike |
| 110 | amplitudes, alternans, or early after depolarization-like phenomena. |

| 112 | Statistical analysis |
| 113 | All data points are shown as the mean value and bars represent the standard error of the mean. A |
| 114 | Student's t-test, paired t-test, or ANOVA was performed where appropriate using GraphPad |
| 115 | Prism 8.3 to determine statistical significance. |
| 116 | RESULTS |
| 117 | ECG evaluation of index patient captures QTc shortening while on Depo |

118 A young woman with LQT2 was referred to Mayo Clinic for evaluation and treatment following

an appropriate VF-terminating ICD shock when she was four-weeks postpartum with her first

120 child. We subsequently discovered and reported her pathogenic variant as p.G1006Afs*49-

121 KCNH2.⁶ Her clinical case is detailed extensively in our previous 2012 case report and is

122 visually represented in **Figure 1**.⁶ At the time of both of her subsequent LQT2-triggered episodes

123 of torsades de pointes and VF, she was receiving Q3-month injectable subcutaneous Depo-

124 Provera for hormonal birth control.

125 Electrocardiogram (ECG) data was obtained from the index patient's electronic medical 126 record as well as dates of Depo injections. Her sentinel event was an out-of-hospital cardiac 127 arrest at the age of 16 years, prompting a secondary prevention ICD through which she has had 128 multiple appropriate defibrillations, most in the context of concurrent Depo use (Figure 1A). 129 The patient's mean lifetime QTc is 520 ms with her maximum recorded QTc at 610 ms. Figure 130 **1B** and **Figure 1C** display a representative ECG while off Depo, demonstrating a QTc of 547 131 ms. This ECG was taken after her appropriate AICD shock while on 50 mg Atenolol (this beta 132 blocker was started elsewhere). A few years later, shortly after another appropriate ICD therapy for VF, her QTc was recorded at 475 ms while receiving Depo injections (Figure 1B and Figure 133 134 **1C**). Generation of p.G1006Afs*49-KCNH2 patient-specific LQT2 iPSC-CM line 135 136 An iPSC cell line was created from the young woman who has the p.G1006Afs*49-KCNH2 137 pathogenic variant. A CRISPR/Cas9 gene-edited/variant-corrected, isogenic control (IC) iPSC 138 line was also created. Immunofluorescence for pluripotency markers (Tra-1-60, SSEA-3, OCT4 139 and Nanog) was confirmed in the p.G1006Afs*49-KCNH2 iPSCs (Figure 2A) and iPSC-CMs 140 demonstrated cardiomyocyte markers (Figure 2B). Sanger sequencing of both p.G1006Afs*49-141 KCNH2 and IC iPSCs confirmed the expected variants (Figure 2C). Additionally, the patient's 142 iPSCs displayed a normal female karyotype (Figure 2D). 143 Treatment with Depo shortens the cellular action potential duration (APD) and field

144 potential duration (FPD) of iPSC-CM models of LQT2.

| 145 | To examine whether Depo alters APD measurements in 2-D cell culture, Fluovolt voltage- |
|-----|--|
| 146 | sensing dye was used to assess p.G1006Afs*49-KCNH2 iPSC-CMs at baseline and after |
| 147 | treatment with 10 μ M Depo. Representative tracings are displayed in Figure 3A . Compared to |
| 148 | baseline (394 \pm 10 ms, n=35), treatment with 10 μ M Depo significantly shortened the APD90 in |
| 149 | the p.G1006Afs*49-KCNH2 iPSC-CMs (303±10 ms, n=42, p<0.0001; Figure 3B, |
| 150 | Supplementary Table 3). Additionally, Depo treatment resulted in shortening of both the |
| 151 | APD50 (baseline: 318±8ms versus Depo: 208±4 ms; p<0.0001) and the APD30 (baseline: 275±7 |
| 152 | ms versus Depo: 175±3 ms; p<0.0001, Figure 3B) in the p.G1006Afs*49-KCNH2 iPSC-CMs. |
| 153 | Similarly, MEA-measured FPD corrected using the Fridericia formula (FPDc) was |
| 154 | significantly shorter in p.G1006Afs*49-KCNH2 iPSC-CMs treated with 10 μ M Depo (364±9 |
| 155 | ms, n=49) compared to untreated p.G1006Afs*49-KCNH2 iPSC-CMs (406±6 ms, n=161, |
| 156 | p=0.003, Figure 4). |
| 157 | Depo treatment with sympathetic stimulation increases the propensity for arrythmia in |
| 158 | p.G1006Afs*49-KCNH2 iPSC-CMs |
| 159 | Erratic beating patterns have been characterized previously in LQT2 human iPSC-CMs using |
| 160 | MEA. ¹⁰ In our study, there was a marked difference in the frequency of erratic beating between |
| 161 | p.G1006Afs*49-KCNH2 (18±5%, n=25) and IC iPSC-CMs (0±0%, n=15, p= 0.0065, Figure 5 , |
| 162 | Supplemental Table 4) under baseline conditions, where each data point represents the sum of |
| 163 | electrodes displaying behavior as a percentage of total beating electrodes. However, there was no |
| 164 | significant change in the erratic beating patterns of the IC iPSC-CMs (0±0%, n=15) following 10 |
| 165 | μ M Depo (1±1%, n=10, p= >0.9999), 1 μ M ISO (14±5%, n=16, p= 0.8337), or combined 10 μ M |
| 166 | Depo + 1 μ M ISO (10±3%, n=13, p= 0.9659) treatment (Supplemental Table 3). |

| 167 | Although there was no significant increase in frequency of erratic beating in the |
|-----|---|
| 168 | G1006Afs*49 iPSC-CMs (18±5%, n=25) following 10 µM Depo (35±8%, n=15, p= 0.5290) or 1 |
| 169 | μ M ISO (39±8%, n=21, p= 0.1515) treatment alone, combined 10 μ M Depo plus 1 μ M ISO |
| 170 | treatment increased significantly the percent of electrodes displaying erratic beating in |
| 171 | p.G1006Afs*49-KCNH2 iPSC-CMs (54±5%, n=38, p=<0.0001, Figure 5, Supplemental |
| 172 | Table 3). |
| 173 | Nadolol treatment reduces propensity of arrhythmia in p.G1006Afs*49-KCNH2 iPSC- |
| 174 | CMs |
| 175 | Per guideline-directed therapy, our patient's original beta blocker therapy with atenolol was |
| 176 | changed to one of the two preferred beta blockers, nadolol. Treatment with 10 μ M nadolol |
| 177 | reduced the frequency of erratic beating observed following 10 μ M Depo plus 1 μ M ISO in |
| 178 | p.G1006Afs*49-KCNH2 iPSC-CMs from 54±5% (n=38) to 36±6% (n=30, p=0.0292, Figure |
| 179 | 6). |
| 180 | DISCUSSION |

181 Herein, we describe for the first time a patient-specific, iPSC-CM study to provide a potential 182 mechanism for a LQT2 patient's clinically documented, Depo-associated episodes of recurrent 183 ventricular fibrillation. Sex hormones, particularly estrogen and progesterone, modulate 184 arrhythmogenic risk in LQTS, though exact mechanisms are complex.⁷ Hormonal culpability is 185 illustrated clearly for women with LQTS in general and LQT2 in particular. For example, their burden of cardiac events is markedly higher during the 9 months post-partum when compared to 186 the 40 weeks before pregnancy or the 40 weeks of pregnancy.¹¹ Additionally, the postpartum 187 188 period is associated with a decrease in progesterone levels compared to levels during pregnancy. 189 Furthermore, progestin-based contraceptives such as the mini-pill and Depo are common forms

of postpartum birth control as they lack the thrombotic risk that estrogen-based contraceptives
 carry.¹² According to the Center for Disease Control, 24% of women ages 15-49 have used
 Depo.¹³

A recent large-scale clinical study found that progestin-only oral contraceptive use in women with LQT2 without concomitant beta blocker use increased risk of recurrent cardiac events by 8-fold.⁴ Despite these new clinical observations, there is a paucity of studies evaluating the biology of hormonal contraception in LQTS women. Herein, we detail the electrophysical properties of the injectable progestin-based contraceptive, Depo, on a novel patient-derived LQT2 iPSC-CM cell model.

In 2012, we described a young woman diagnosed with LQT2 who experienced multiple 199 episodes of ventricular fibrillation while receiving Q-3 month injections of Depo for hormonal 200 201 contraception.⁶ The patient has an LQT2-causative pathogenic variant in *KCNH2* resulting from 202 a single-nucleotide deletion causing a frameshift mutation and subsequent amino acid C-203 terminus truncation, annotated as G1006Afs*49. Canonically, frameshift variants such as 204 p.G1006Afs*49-KCNH2 result in haploinsufficiency via non-sense mediated decay. However, recent in vitro data suggests that p.G1006Afs*49-KCNH2 does not follow this rule. 205 206 Interestingly, the work by Zio et al. demonstrates that p.G1006Afs*49-KCNH2 results in a 207 truncated Kv11.1/hERG protein capable of reaching the plasma membrane where it exerts a dominant-negative effect.¹⁴ 208 209 The patient's QTc was notably shorter while on Depo. To determine if our cellular model

210 recapitulated this clinical phenotype, we evaluated the patient's iPSC-CMs with Depo treatment.
211 After successful creation of the patient's p.G1006Afs*49-KCNH2 iPSC-CM line, cellular

212 measurements of APD and FPDc were used as a cellular surrogate for the QT interval.

Consistent with the patient's clinical phenotype, Depo treatment shortened both the APD and
FPDc in her p.G1006Afs*49-KCNH2 iPSC-CMs.

215 Until now, the synthetic progestin Depo has not been evaluated for its effects on the 216 cardiac APD. However, endogenous progesterone shortens the QT interval through a variety of 217 mechanisms including activation of slow delayed rectifier potassium currents (I_{Ks}) and inhibition of L-type calcium channels (I_{Ca-L}).^{7, 15, 16} Studies using guinea pig ventricular myocytes have 218 219 demonstrated that these nongenomic actions of progesterone work via a nitric-oxide synthase signal transduction pathway.¹⁷ Furthermore, progesterone binding to sigma-receptors modulates 220 voltage-gated sodium ion current, enhancing its OT-shortening effect.¹⁸ Additionally, LOT2 221 222 rabbit studies reveal antiarrhythmic progesterone effects (mainly due to APD-shortening and SERCA activation).¹⁹ Clinical studies corroborate the QT-shortening effect of endogenous 223 progesterone.^{20, 21} Furthermore, progesterone was protective against drug-induced QT 224 prolongation in a randomized double-blind placebo study with healthy women.²² 225 226 As Depo is a synthetic progestin, it exerts many progestogenic antiproliferative effects on 227 the uterine endometrium conferring its high efficacy as a contraceptive. However, from a 228 cardiovascular standpoint, the effects of Depo are often opposite from endogenous progesterone, warranting these hormones' individual evaluation on arrhythmogenic risk.²³ Our results of Depo-229 230 mediated APD shortening in an iPSC-CM model cast new light on the effect of Depo in LQTS 231 and align its QT-action with that of progesterone. The specific mechanism for this Depomediated APD shortening remains elusive and should prompt further mechanistic evaluation, 232 233 however, its actions may be like endogenous progesterone. With our data, one might expect 234 postpartum use of Depo to shorten the QT interval, but this paradox of increased cardiac events

in our patient and her cardiomyocytes may be due to variable spatial distribution and effect of thehormone leading to transmural heterogeneity.

237 Genotype-phenotype correlation studies have demonstrated that LQT2 patients are at 238 increased risk of cardiac events with sudden auditory triggers, believed to be mediated through 239 beta-adrenergic stimulation and ameliorated with beta-adrenergic antagonists such as beta 240 blockers (β -blockers). LQT2 women are predisposed to life-threatening arrythmias such as torsades de point, especially at times of sudden arousal and heightened sympathetic activity.²⁴ 241 242 Therefore, we used the beta-adrenergic agonist, isoproterenol (ISO), to mimic this adrenergic surge that places LQT2 patients at increased risk of cardiac events.²⁵ When treated with Depo 243 244 plus ISO, a 3-D cellular syncytium of p.G1006Afs*49-KCNH2 iPSC-CMs showed a significant increase in erratic beating activity. Interestingly, there was no significant change in the erratic 245 246 beating patterns of the IC iPSC-CMs following treatment with Depo and ISO. One strength of 247 evaluating the cardiomyocytes in MEA, over other single-cell methods, is the ability to record 248 electrophysiologic properties from a cellular syncytium. Although the canonical mechanism of 249 action potential prolongation digressing into a dangerous arrythmia such as torsades de pointes is 250 via an EAD- or delayed after depolarization (DAD)-mechanism, it is possible that Depo is 251 shortening the APD of individual cells to varying degrees leaving a multi-layered, cellular 252 syncytium vulnerable to heterogeneous refractory periods in the wells. Clinically, this could 253 mean that during sympathetic stimulation, Depo's progesterone-like attenuation of the QT 254 interval is being countered by a pro-arrhythmic accentuation in transmural dispersion of 255 repolarization culminating in the clinical observation of increased LQTS-triggered cardiac events 256 in women using this form of contraception. Adding to the complexity, Depo binds to other 257 steroid receptors, including glucocorticoid and estrogen receptors, leading to another potential

| 258 | mechanism of Depo's arrhythmogenicity in this patient's cells and a potential source of follow- |
|-----|--|
| 259 | up studies. ²⁶ As studies in LQT2 and wildtype rabbits revealed that estradiol exerts |
| 260 | proarrhythmic effects by increasing I_{Ca-L} and sodium calcium exchanger NCX activity and |
| 261 | expression thereby facilitating EADs ^{19,16} , Depo might exert some of its proarrhythmic effects |
| 262 | also via its agonistic binding to estrogen receptors. |
| | |

263 Nonselective beta-adrenoreceptor antagonists (β -blockers), such as nadolol, are first-line pharmacologic agents for LQTS in general including LQT2.²⁷ After each of her recurrent cardiac 264 events, the index patient was briefly on nadolol therapy, which was discontinued due to 265 266 symptomatic intolerance. Of note, both incidences of the patient's Depo-associated cardiac 267 events happened following β -blocker cessation. Our study demonstrates that in the presence of 268 combined Depo and ISO, nadolol treatment reduces the frequency of erratic beating in 269 p.G1006Afs*49-KCNH2 cardiomyocytes. This is similar to nadolol's ability to ameliorate 270 electrophysiological abnormalities in isoprenaline-treated human iPSC-CMs as measured by MEA.10 271

272 β-blocker therapy significantly attenuates the risk of cardiac events in women diagnosed with LQTS taking progestin-only oral contraceptives.⁴ Given our findings, it is possible that 273 274 Depo, also a progestin-only form of contraception, might pose similar arrhythmogenic risk to 275 women with LQT2 and β -blocker therapy might mitigate these risks. Since our patient was on 276 Depo without β -blocker coverage, this may have left her with a particularly vulnerable 277 arrhythmogenic risk profile, and we believe that the use of Depo in the setting of adrenergic stimulation in the absence of β -blocker therapy could have precipitated her cardiac events. 278 279 Furthermore, arrhythmias always occurred during the postpartum period (in which she received 280 the medroxyprogesterone acetate); and therefore, the pro-arrhythmic triggers may be even more

complex as during the postpartum several other potentially pro-arrhythmic hormones are at play,
such as oxytocin and prolactin that both block I_{Ks}.²⁸

283 Although the study by Goldenberg et al. did not evaluate Depo, it suggests the 284 formulation of the contraceptives matters, specifically finding progestin-only oral contraceptives to carry the largest risk to LQT2 women.⁴ Other studies have determined that oral-contraceptive 285 286 QT-mediation may depend on the progestin androgenicity, specifically that pro-androgenic firstand second-generation oral contraceptives shorten the QTc, while anti-androgenic fourth-287 generation oral contraceptives lengthen the OTc.²⁹ Depo has been shown to be androgenic, while 288 289 progesterone is antiandrogenic. Our observation of Depo shortening the QTc in our patient and 290 shortening the APD in our cells matches with other observations of pro-androgenic contraceptives, potentially suggesting that Depo's hormonal influence and arrhythmogenic 291 potential may extend beyond its shared-chemical origin with progesterone.^{17, 21} The similar and 292 293 dissimilar characteristics of exogenous progestins as it pertains to channelopathies are complex, 294 and further studies are needed to parse apart the differential action of progestin-based 295 contraceptives, Depo included.

296 CONCLUSION

This study marks the first-ever 'disease in a dish' model of the injectable contraceptive DepoProvera (Depo) in LQTS. Although the concentration of Depo used here with iPSC-CM cellular
models is significantly higher than the plasma concentrations measured in preclinical animal
models, our results indicate that Depo induces erratic beating patterns in human patient-derived
re-engineered heart tissue under sympathetic, β-adrenergic stimulation with isoproterenol. βadrenergic antagonism with nadolol treatment significantly attenuates this erratic beating
frequency in LQT2 patient-derived iPSC-CMs treated with Depo and isoproterenol. Further

- 304 large-scale prospective clinical evaluations of Depo's pro-arrhythmic potential are needed as
- 305 well as a detailed mechanistic study of this hormone's pathophysiology as it pertains to LQTS.

С

SUPPLEMENTAL MATERIAL

SUPPLEMENTAL METHODS

Generation, Maintenance, and Quality Control of Reprogrammed iPSCs

Patient PBMCs were processed and stored in liquid nitrogen by the Mayo Clinic Regenerative Medicine Biotrust Facility. Frozen PBMCs were thawed quickly and reprogramed via transduction into induced pluripotent stem cells (iPSCs) using the CytoTune-iPS 2.0 Sendai Reprogramming kit. Colonies were picked 2 weeks after nucleofection with Yamanaka's factors. Following reprogramming and expansion of single colonies, Sanger sequencing in both clones derived from the index patient confirmed the mutation, p.G1006Afs*49-KCNH2, using primer sequences as shown in **Supplemental Table 1**. Immunostaining with pluripotency markers, Nanog, SSEA4, Tra-160, Oct4 showed expression in all clones (**Supplemental Table 2**).

iPSCs were cultured in mTeSR Plus [STEMCELL; Vancouver, Canada] supplemented with 1% antibiotic/antimycotic solution on Matrigel-coated [Corning; Corning, NY] 6-cm culture and 6-well dishes in a 5% CO₂ incubator at 37°C. At 80-90% confluence, iPSCs were passaged using ReLeSR [STEMCELL Technologies, 05872].

Generation of CRISPR-Cas9 Variant Corrected Isogenic Control

Isogenic "variant corrected" control iPSCs were generated using CRISPR-Cas9 technology via contract with Applied Stem Cell [Applied Stem Cell, Milpitas, CA]. Guide RNAs (gRNAs) for this G1006Afs*49 line were designed, validated in vivo, and one candidate gRNA was selected for genome editing the patient iPSC line (**Supplemental Table 1**). A single-stranded oligodeoxynucleotide (SSODN) was designed as a repair template and a silent mutation in the gRNA binding site was created to prevent re-cutting (**Supplemental Table 1**). The

G1006Afs*49 patient line was transfected with the gRNAs and ssODN constructs before undergoing puromycin selection. Single-cell colonies were genotyped and mutation correction clones were expanded for future studies.

iPSC-CM Differentiation, Culture, and Dissociation

As previously published, iPSCs were cultured in 6-well plates and differentiated into cardiomyocytes (CMs) at 85% confluency.¹ On day 0 of differentiation, culture media was changed from mTeSR-Plus to RPMI 1640 GlutaMAX plus 25mM HEPES supplemented with B27-minus insulin (RPMI/B27-ins) [Thermo] containing 5 μ M CHIR99021 [MilliporeSigma; St. Louis, MO]. On day 2 (following 48 hours), media was changed to RPMI/B27-ins containing 5 μ M IWP-2 [MilliporeSigma]. On day 4, the medium was changed back to the maintenance medium RPMI/B27-ins. Spontaneous beating began on days 7-10. Once beating, CMs were dissociated enzymatically using STEMdiff cardiomyocyte dissociation kit [STEMCELL] as previously described.¹ After 24 hours, cells were maintained in RPMI/B27+ins medium. Immunostaining of CMs following plating on an 8-well chamber slide demonstrated staining of Cardiac Troponin-T (cTnT) and α -Actinin (**Supplemental Table 2**). Isogenic control cell line data is included in **Supplemental Figure 1**.

Voltage Dye Optical Action Potentials in iPSC-CMs

iPSC-CMs were plated at 400,000 cells/dish on Matragel-coated 35 mm glass-bottom culture dishes. Prior to imaging, CMs were washed with pre-warmed (37°C) HEPES-buffered Tyrode's solution [Alfa Aesar; Haverhill, MA]. Each 35mm glass-bottom dish was incubated at 37°C in the dark for 20min with 0.5µL FluoVolt dye, 5µL PowerLoad, and 0.5mL Tyrode's solution [FluoVolt Membrane Potential kit, Thermo]. Excess dye was rinsed three times with Tyrode's solution, and a final 1.5mL Tyrode's solution was added to the iPSC-CMs for imaging. Depo

was prepared fresh daily at 4X in pre-warmed tyrode solution for a final concentration of 10 μ M. During imaging, the dishes were kept in a heated 37°C stage-top chamber [Live Cell Instrument; Seoul, South Korea] with 5% CO₂. Under 40X-water objective magnification, using a Nikon Eclipse Ti light microscope [Nikon; Tokyo, Japan], optical action potentials were recorded in 20s fast time-lapse videos at a rate of 50 frames/sec (fps, 20ms exposure time) with LED illumination at 5% power. iPSC-CMs were paced at 1Hz (9ms pulse duration, 25V) using a MyoPacer field stimulator [Ion Optix; Westwood, MA] to eliminate beat-rate dependent effects on the APD. Small rectangular regions of interest were drawn over flashing areas of single cells for analysis. The NIS-Elements software [Nikon] was used to measure the fluorescence intensity over time within each region of interest, resulting in optical action potential traces. The traces were corrected for photobleaching and the amplitude was normalized as change in fluorescence divided by the baseline minimum fluorescence ($\Delta F/F_{min}$) using an in-house custom Excel program. Common action potential parameters including APD₉₀, APD₅₀, amplitude, rise time, upstroke velocity, etc. were detected for each individual optical action potential and averaged across all beats within a 20s trace. The average of all beats within a 20s trace represents a single data point. For representative traces, the maximum amplitude was further normalized to 1.0 to allow for accurate visualization of APD differences.

Multi-Electrode Array (MEA) Measurement

iPSC-CMs were dissociated and seeded at 50,000 cells per well on 48-well Biocircuit MEA plate (Axion BioSystems, Inc. M768-BIO-48) pre-coated with Matrigel. Cells were cultured in a humidified incubator at 37°C and 5% CO₂ for 7-10 days after dissociation, and media was changed every 2 days. Media was changed 1-4 hours before starting experiment and the MEA plate was placed in Maestro MEA device (Axion BioSystems, Inc.) with automatically adjusted

and controlled environment (37°C and 5%CO₂), and equilibrated for at least 20 minutes before baseline recordings.

All testing compounds were prepared fresh on each day of the experiment in warm RPMI+ins culture media. Medroxyprogesterone Acetate (Selleck Chemicals Catalog No. S2567), aka Depo, was diluted to 20 μ M (2X) and added to the testing well at equal volume creating a final concentration of 10 μ M. Depo-treated wells were allowed to rest in the MEA climatecontrolled machine for 30 minutes before recording. Isoproterenol was diluted to 2 μ M (2X) and added to the testing wells at equal volume creating a final concentration of 1 μ M. Wells with Depo + ISO were diluted at 4X for the same final concentrations based on the concentrations and volumes already present in the wells. Nadolol [Sigma-Aldrich Solutions Catalog No. 1449700] was added to Depo+ISO treated wells at time of Iso treatment for a final concentration of 10 μ M. MEA measurements were taken on the field potential configuration and recorded for 20 seconds from 10-12 minutes from the time ISO was added. The Cardiac Analysis Tool (Axion BioSystems, Inc. Version 3.1.4) was used for data analysis.

Statistical Analysis

GraphPad Prism 9 was used for all statistical analyses. Individual data points shown where appropriate as well as the mean \pm standard error (SEM). Statistical analysis methods are specified in each figure legend, but 1-way ANOVA with multiple comparisons was compared when comparing >2 groups and an unpaired Student's t-test was used when comparing 2 groups. A P<0.05 was considered statistically significant.

| | n=25 | n=38 | n=15 | n=21 |

Supplementary Table 4 | Expanded Data for LQT2 iPSC-CMs with Multi-Electrode Array (MEA).

Values listed demonstrate averages \pm SEM. N represents number technical replicates of independent wells. Each well contains 16 total recording electrodes, if electrode was not beating, it was excluded from denominator in frequency calculation. Erratic beating frequency was defined as dropped beats, alternans, or early after depolarization-like phenomena. Depo-treated wells were pretreated with 10 μ M Depo for 30 minutes before treatment and incubation with 1 μ M ISO for 10-12 minutes at time of measurement. Number of independent experiments are as follows: Isogenic Control= 3, p.G1006Afs*49-KCNH2 clone #1= 3, p.G1006Afs*49-KCNH2 clone #2= 1.
