Fiducial and differential cross sections of Higgs boson production measured in the four-lepton decay channel in $pp$ collisions at $\sqrt{s} = 8$ TeV with the ATLAS detector

The ATLAS Collaboration

Abstract

Measurements of fiducial and differential cross sections of Higgs boson production in the $H \rightarrow ZZ^* \rightarrow 4\ell$ decay channel are presented. The cross sections are determined within a fiducial phase space and corrected for detection efficiency and resolution effects. They are based on 20.3 fb$^{-1}$ of $pp$ collision data, produced at $\sqrt{s} = 8$ TeV centre-of-mass energy at the LHC and recorded by the ATLAS detector. The differential measurements are performed in bins of transverse momentum and rapidity of the four-lepton system, the invariant mass of the subleading lepton pair and the decay angle of the leading lepton pair with respect to the beam line in the four-lepton rest frame, as well as the number of jets and the transverse momentum of the leading jet. The measured cross sections are compared to selected theoretical calculations of the Standard Model expectations. No significant deviation from any of the tested predictions is found.

The ATLAS Collaboration

Abstract

Measurements of fiducial and differential cross sections of Higgs boson production in the $H \rightarrow ZZ^* \rightarrow 4\ell$ decay channel are presented. The cross sections are determined within a fiducial phase space and corrected for detection efficiency and resolution effects. They are based on 20.3 fb$^{-1}$ of $pp$ collision data, produced at $\sqrt{s} = 8$ TeV centre-of-mass energy at the LHC and recorded by the ATLAS detector. The differential measurements are performed in bins of transverse momentum and rapidity of the four-lepton system, the invariant mass of the subleading lepton pair and the decay angle of the leading lepton pair with respect to the beam line in the four-lepton rest frame, as well as the number of jets and the transverse momentum of the leading jet. The measured cross sections are compared to selected theoretical calculations of the Standard Model expectations. No significant deviation from any of the tested predictions is found.

1. Introduction

In 2012 the ATLAS and CMS collaborations announced the discovery of a new particle $\text{H}$ in the search for the Standard Model (SM) Higgs boson at the CERN Large Hadron Collider (LHC) [1, 2]. Since this discovery, the particle’s mass $m_H$ was measured by the ATLAS and CMS collaborations [3–8]. The result of the ATLAS measurement based on 25 fb$^{-1}$ of data collected at centre-of-mass energies of 7 TeV and 8 TeV is $125.36 \pm 0.41$ GeV. Tests of the couplings and spin/CP quantum numbers have been reported by both collaborations [11, 13, 14] and show agreement with the predicted scalar nature of the SM Higgs boson.

In this Letter, measurements of fiducial and differential production cross sections for the $H \rightarrow ZZ^* \rightarrow 4\ell$ decay channel are reported and compared to selected theoretical calculations. The event selection and the background determination are the same as in Ref. [15], where a detailed description is given. For this measurement, an integrated luminosity of 20.3 fb$^{-1}$ of $pp$ collisions is analysed. The data were collected at the LHC at a centre-of-mass energy of $\sqrt{s} = 8$ TeV and recorded with the ATLAS detector [16].

The ATLAS detector covers the pseudorapidity range $|\eta| < 4.9$ and the full azimuthal angle $\phi$. It consists of an inner tracking detector covering the pseudorapidity range $|\eta| < 2.5$ surrounded by a superconducting solenoid, electromagnetic and hadronic calorimeters, and an external muon spectrometer with large superconducting toroidal magnets.

Fiducial cross sections are quoted to minimize the model dependence of the acceptance corrections related to the extrapolation to phase-space regions not covered by the detector. The measured fiducial cross sections are corrected for detector effects to be directly compared to theoretical calculations.

The differential measurements are performed in several observables related to the Higgs boson production and decay. These include the transverse momentum $p_T$ and rapidity $y$ of the Higgs boson.
The Higgs boson branching fractions for decays to four-lepton final states are provided by PROPHECY4F [46, 47], which implements the complete NLO QCD+EW corrections and interference effects between identical final-state fermions.

The $H \rightarrow ZZ^{∗} \rightarrow 4\ell$ signal is modelled using the POWHEG Monte Carlo (MC) event generator [48–52], which calculates separately the ggF and VBF production mechanisms with matrix elements up to NLO. The description of the Higgs boson transverse momentum spectrum in the ggF process is adjusted to follow the calculation in Ref. [19, 20], which includes QCD corrections up to NLO and QCD soft-gluon resummations up to NNLL, as well as finite quark masses [53]. POWHEG is interfaced to PYTHIA8 [54] for showering and hadronization, which in turn is interfaced to PHOTOS [55, 56] to model photon radiation in the final state. PYTHIA8 is used to simulate $VH$ and $tH$ production. The response of the ATLAS detector is modelled in a simulation [57] based on GEANT4 [58].

The measured fiducial cross-section distributions are compared to three ggF theoretical calculations: POWHEG without the adjustments to the $p_{T,H}$ spectrum described above, POWHEG interfaced to MINLO (Multi-scale improved NLO) [59] and HRES2 (v.2.2) [19, 20]. POWHEG with MINLO provides predictions for jet-related variables at NLO for Higgs boson production in association with one jet. The HRES2 program computes fixed-order cross sections for ggF SM Higgs boson production up to NNLO. All-order resummation of soft-gluon effects at small transverse momenta is consistently included up to NNLL, using dynamic factorization and resummation scales. The program implements top- and bottom-quark mass dependence up to NLL+NNLO. At NNLL+NNLO level only the top-quark contribution is considered. HRES2 does not perform showering and QED final-state radiation effects are not included.

The contributions from the other production modes are added to the ggF predictions. At a centre-of-mass energy of 8 TeV and for a Higgs boson mass of 125.4 GeV, their relative contributions to the total cross section are 87.3% (ggF), 7.1% (VBF), 3.1% ($WH$), 1.9% ($ZH$) and 0.6% ($ttH$), respectively.

All theoretical predictions are computed for a SM Higgs boson with mass 125.4 GeV. They are normalized to the most precise SM inclusive cross-section predictions currently available [60], corrected for the fiducial acceptance derived from the
simulation.

The $ZZ$, $WZ$, $tt$ and $Z + \text{jets}$ background events are modelled using the simulated samples and cross sections described in Ref. 15.

3. Event selection

The detector level physics object definitions of muons, electrons, and jets, and the event selection applied in this analysis are the same as in Ref. 15, with the exception of the jet selection and the additional requirement on the four-lepton invariant mass described below. A brief overview is given in this section.

Events with at least four leptons are selected with single-lepton and dilepton triggers. The transverse momentum and transverse energy thresholds for the single-muon and single-electron triggers are 24 GeV. Two dimuon triggers are used, one with symmetric thresholds at 13 GeV and the other with asymmetric thresholds at 18 GeV and 8 GeV. For the dielectron trigger the symmetric thresholds are 12 GeV. Furthermore there is an electron–muon trigger with thresholds at 12 GeV (electron) and 8 GeV (muon).

Higgs boson candidates are formed by selecting two same-flavour opposite-sign (SFOS) lepton pairs (a lepton quadruplet). The leptons must satisfy identification, impact parameter, and track-based and calorimeter-based isolation criteria. Each muon (electron) must satisfy transverse momentum $p_T > 6$ GeV (transverse energy $E_T > 7$ GeV) and be in the pseudorapidity range $|\eta| < 2.7$ (2.47). The highest-$p_T$ lepton in the quadruplet must satisfy $p_T > 20$ GeV, and the second (third) lepton in $p_T$ order must satisfy $p_T > 15$ (10) GeV. The leptons are required to be separated from each other by $\Delta R = \sqrt{(\Delta \eta)^2 + (\Delta \phi)^2} > 0.1$ (0.2) when having the same (different) lepton flavours.

Multiple quadruplets within a single event are possible: for four muons or four electrons there are two ways to pair the masses, and for five or more leptons there are multiple combinations. The quadruplet selection is done separately in each channel: $4\mu$, $2e2\mu$, $2\mu2e$, $4e$, keeping only a single quadruplet per channel. Here the first flavour index refers to the leading lepton pair, which is the pair with the invariant mass $m_{12}$ closest to the $Z$ boson mass [61]. The invariant mass $m_{12}$ is required to be between 50 GeV and 106 GeV. The subleading pair of each channel is chosen as the remaining pair with mass $m_{34}$ closest to the $Z$ boson mass and satisfying the requirement $12 < m_{34} < 115$ GeV. Finally, if more than one channel has a quadruplet passing the selection, the channel with the highest expected signal rate is kept, in the order: $4\mu$, $2e2\mu$, $2\mu2e$, $4e$. A $J/\psi$ veto is applied: $m(\ell_i, \ell_j) > 5$ GeV for SFOS lepton pairs. Only events with a four-lepton invariant mass in the range 118–129 GeV are kept. This requirement defines the signal mass window and was chosen by minimizing the expected uncertainty on the total signal yield determination, taking into account the experimental uncertainty on the Higgs boson mass.

Jets are reconstructed from topological clusters of calorimeter cells using the anti-$k_t$ algorithm [62] with the distance parameter $R = 0.4$. In this analysis, jets [62] are selected by requiring $p_T > 30$ GeV, $|y| < 4.4$ and, in order to avoid double counting of electrons that are also reconstructed as jets, $\Delta R(\text{jet, electron}) > 0.2$.

The events are divided into bins of the variables of interest, which are computed with the reconstructed four-momenta of the selected lepton quadruplets or from the reconstructed jets: the transverse momentum $p_T^{\text{reco}}$ and the rapidity $y^{\text{reco}}$ of the four-lepton system, the invariant mass of the subleading lepton pair $m_{34}^{\text{reco}}$, the magnitude of the cosine of the decay angle of the leading lepton pair in the four-lepton rest frame with respect to the beam axis $|\cos \theta^{\text{reco}}|$, the number of jets $n_j^{\text{reco}}$, and the transverse momentum of the leading jet $p_T^{\text{jet}}$. In order to distinguish them from the unfolded variables used in the cross section bin definition, they are labelled with “reco”.

4. Definition of the fiducial region

The fiducial selection, outlined in Table 1, is designed to replicate at simulation level, before applying detector effects, the analysis selection as closely as possible in order to minimize model-dependent acceptance effects on the measured cross sections.

The fiducial selection is applied to electrons and muons originating from vector-boson decays before they emit photon radiation, referred to as Born-level leptons. An alternative approach would be to correct the lepton momenta by adding final-state radiation photons within a cone of size $\Delta R < 0.1$ around each lepton (dressing). For this analysis the acceptance difference between Born and dressed-lepton definitions is less than 0.5%. Particle-level jets are reconstructed from all stable particles ex-
Table 1: List of selection cuts which define the fiducial region of the cross section measurement. Same flavor opposite sign lepton pairs are denoted as SFOS, the leading lepton pair mass as $m_{12}$, and the subleading lepton pair mass as $m_{34}$.

| Lepton selection | Muons: $p_T > 6$ GeV, $|\eta| < 2.7$ | Electrons: $p_T > 7$ GeV, $|\eta| < 2.47$ |
|------------------|-------------------------------------|-------------------------------------|
| Lepton pairing   | Leading pair: SFOS lepton pair with smallest $|m_Z - m_{12}|$ | Subleading pair: Remaining SFOS lepton pair with smallest $|m_Z - m_{14}|$ |
| Event selection  | Lepton kinematics: $p_T > 20, 15, 10$ GeV | Mass requirements: 50 < $m_{12}$ < 106 GeV, 12 < $m_{34}$ < 115 GeV |
|                  | Lepton separation: $\Delta R(\ell_i, \ell_j) > 0.1$ (0.2) for same- (different-) flavour leptons | $J/\psi$ veto: $m(\ell_i, \ell_j) > 5$ GeV for all SFOS lepton pairs |
|                  | Mass window: 118 < $m_{4\ell}$ < 129 GeV |

The background estimates used in this analysis are described in detail in Ref. [12]. The irreducible $ZZ$ and the reducible $WZ$ background contributions are estimated using simulated samples normalized to NLO predictions. For the jet-related variables, the simulation predictions are compared to data for $m_{4\ell} > 190$ GeV where the $ZZ$ background process is dominant; shape differences between the distributions in data and simulation are used to estimate systematic uncertainties.

The reducible $Z +$ jets and $t\bar{t}$ background contributions are estimated with data-driven methods. Their normalizations are obtained from data control regions and extrapolated to the signal region using transfer factors. The $\ell\ell + \mu\mu$ final state is dominated by $Z +$ heavy-flavour jets and the $\ell\ell + ee$ final state by $Z +$ light-flavour jets. The misidentification of light-flavour jets as electrons is difficult to model in the simulation. Therefore the distributions for $\ell\ell + ee$ are taken from data control regions and extrapolated to the signal region, while the background distributions for $\ell\ell + \mu\mu$ are taken from simulated samples.

The observed distributions are compared to the signal and background expectations for the six reconstructed observables $p_T^{\mu\mu}$, $|y_H^{\mu\mu}|$, $m_{34}^{\mu\mu}$, $|\cos \theta_2^{\mu\mu}|$, $n_{jets}$, and $p_T^{\mu\mu}$ are shown in Fig. 1. The signal prediction includes VBF, $ZH$, $WH$, $ttH$, and the POWHEG ggF calculation for a Higgs boson with $m_H = 125$ GeV and is normalized to the most precise SM inclusive cross-section calculation currently available [21].
Fig. 1: Data yield distributions for the transverse momentum $p_{T,\text{reco}}$ and the rapidity $|y_{\text{reco}}|$ of the four-lepton system, the invariant mass of the subleading lepton pair $m_{34}^{\text{reco}}$, the magnitude of the cosine of the decay angle of the leading lepton pair in the four-lepton rest frame with respect to the beam axis $|\cos \theta^{\text{reco}}|$ the number of jets $n_{\text{reco jets}}$ and the transverse momentum of the leading jet $p_{T,jet}^{\text{reco}}$ compared to signal and background expectations. The signal prediction includes VBF, $ZH$, $WH$, $t\bar{t}H$, and the Powheg ggF calculation for a Higgs boson with $m_H=125$ GeV and is normalized to the most precise SM inclusive cross-section calculation currently available [60]. The hatched areas denote the systematic uncertainties on the backgrounds.
6. Observed differential yields and unfolding

The extraction of the signal yield for the measurement of the fiducial cross section is performed through a fit to the $m_4\ell$ distribution using shape templates for the signal and background contributions \[ \text{[13]} \]. In this fit, the Higgs boson mass is fixed to 125.4 GeV and the parameter of interest is the total number of signal events. The extracted number of observed signal events in the mass window is $23.7^{+5.9}_{-5.3}\,(\text{stat.})\pm 0.6\,(\text{syst.})$.

In the differential cross-section measurements, given the low number of signal events expected in each measured bin $i$, the signal yields $N_i^{\text{sig}}$ are determined by subtracting the expected number of background events from the observed number of events. This is done within the mass window for each bin of the observable of interest. The total number of observed events in the mass window is 34 and the extracted signal yield is $25.1^{+6.3}_{-5.4}\,(\text{stat.})^{+0.6}_{-0.4}\,(\text{syst.})$ events.

The difference between the number of signal events extracted with the two methods is mainly due to fixing the Higgs boson mass to 125.4 GeV in the fit method. As reported in Ref. \[ \text{[10]} \], the best fit mass in the $H \rightarrow ZZ^* \rightarrow 4\ell$ channel alone is 124.5 GeV, causing smaller weights for some events in the fit.

After subtracting the background, the measured signal yields are corrected for detector efficiency and resolution effects. This unfolding is performed using correction factors derived from simulated SM signal samples. The correction factor in the $i$-th bin is calculated as

\[ c_i = \frac{N_i^{\text{reco}}}{N_i^{\text{fid}}}, \]

where $N_i^{\text{reco}}$ is the number of reconstructed events in the $i$-th bin of the observed distribution and $N_i^{\text{fid}}$ is the number of events in the $i$-th bin of the particle-level distribution, within the fiducial region.

The unfolded signal yield in each bin is then converted into a differential fiducial cross section via

\[ \frac{d\sigma_{\text{fid},i}}{dx_i} = \frac{N_i^{\text{sig}}}{c_i \cdot L_{\text{int}} \cdot \Delta x_i}, \]

where $\Delta x_i$ is the bin width and $L_{\text{int}}$ the integrated luminosity.

The correction factors used in this analysis are obtained from simulated samples for all SM Higgs production modes, using the relative rates as predicted by the SM. The inclusive correction factor is $c = 0.553 \pm 0.002\,(\text{stat.}) \pm 0.015\,(\text{syst.})$. The correction factors for the different production modes are $0.553\,(\text{ggF}), 0.572\,(\text{VBF}), 0.535\,(\text{WH}), 0.551\,(\text{ZH})$ and $0.417\,(ttH)$. In $ttH$ production the Higgs boson is accompanied by light- and heavy-flavour jets as well as possible additional leptons from the top-quark decays. Since lepton isolation is applied to the reconstructed but not the fiducial objects, the correction factors for $ttH$ differ from those for the other production modes.

For each bin, the number of expected background events, the number of observed events, the luminosity, and the correction factors are used to calculate a profile likelihood ratio \[ \text{[64]} \]. The likelihood includes shape and normalization uncertainties of backgrounds and correction factors as nuisance parameters. For each variable all bins are included in the likelihood and correlations of uncertainties between the different bins and between backgrounds and correction factors are taken into account. The cross sections are extracted for each bin by minimizing twice the negative logarithm of the profile likelihood ratio $-2\ln \Lambda$. The uncertainties on the cross sections are also estimated using $-2\ln \Lambda$ by evaluating its variation as a function of the parameter of interest (the cross section value in each bin). Under the asymptotic assumption \[ \text{[64]} \], $-2\ln \Lambda$ behaves as a $\chi^2$ distribution with one degree of freedom. For some of the fitted intervals, due to the low number of events, the distribution of the profile likelihood ratio does not follow a $\chi^2$ distribution and the uncertainties are derived using pseudo-experiments.

The compatibility between the measured cross sections and the theoretical predictions is evaluated by computing the difference between the value of $-2\ln \Lambda$ at the best-fit value and the value obtained by fixing the cross sections in all bins to the ones predicted by theory. Under the asymptotic assumption \[ \text{[64]} \], this statistical observable behaves as a $\chi^2$ distribution with the number of degrees of freedom equal to the number of bins; it is used as a test statistic to compute the $p$-values quantifying the compatibility between the observed distributions and the predictions. For all measured observables the asymptotic assumption is verified with pseudo-experiments.

7. Systematic uncertainties

Systematic uncertainties are calculated for the estimated backgrounds, the correction factors, and
Fig. 2: Differential unfolded cross sections for the transverse momentum $p_T\mu$ and rapidity $y_H$ of the Higgs boson, the invariant mass of the subleading lepton pair $m_{34}$, the magnitude of the cosine of the decay angle of the leading lepton pair in the four-lepton rest frame with respect to the beam axis $|\cos \theta^*|$, the number of jets $n_{ jets}$, and the transverse momentum of the leading jet $p_{T,jet}$ in the $H \to ZZ^* \to 4\ell$ decay channel compared to different theoretical calculations of the ggF process: POWHEG, MINLO and HRRes2. The contributions from VBF, $ZH/WH$ and $t\bar{t}H$ are determined as described in Section 2 and added to the ggF distributions. All theoretical calculations are normalized to the most precise SM inclusive cross-section predictions currently available [60]. The error bars on the data points show the total (stat.+$\pm$ syst.) uncertainty, while the grey bands denote the systematic uncertainties. The bands of the theoretical prediction indicate the total uncertainty.
the SM theoretical predictions; the latter only have an impact on the quantitative comparison of the measurements with different predictions. An overview of the systematic uncertainties on the total background prediction and the correction factors is shown in Table 2.

Table 2: Summary of the relative systematic uncertainties on the total background contribution (top rows) and on the parameters that enter the signal extraction (bottom rows). The ranges indicate the variation across observables and bins.

The uncertainty on the integrated luminosity is propagated in a correlated way to the backgrounds evaluated from the MC predictions and to the unfolding, where it is used when converting the estimated unfolded signal yield into a fiducial cross section. This uncertainty is derived following the same methodology as that detailed in Ref. [15] from a preliminary calibration of the luminosity scale derived from beam-separation scans performed in November 2012.

Systematic uncertainties on the data-driven estimate of the reducible backgrounds are assigned both to the normalization and the shapes of the distributions by varying the estimation methods [12].

The systematic uncertainties on the lepton trigger, reconstruction and identification efficiencies [66, 67] are propagated to the signal correction factors and the \( ZZ^* \) background, taking into account correlations. For the correction factors, systematic uncertainties are assigned on the jet resolution and energy scales. The largest systematic uncertainty is due to the uncertainty in the jet flavour composition [63, 68, 69].

The uncertainties on the correction factors due to PDF choice as well as QCD renormalization and factorization scale variations are evaluated in signal samples using the procedure described in Ref. [15] and found to be negligible. A similar procedure is followed for most variables for the irreducible \( ZZ \) background. For the jet-related observables an uncertainty is derived instead by comparing the data with the predicted \( ZZ \) distributions for \( m_{4\ell} > 190 \) GeV, after normalizing the MC estimate to the observed data yield. The systematic uncertainty is estimated as the larger of the data-MC difference and the statistical uncertainty on the data. This systematic uncertainty accounts for both the theoretical and experimental uncertainties in the modelling of the \( ZZ \) jet distributions. Systematic uncertainties due to the modelling of QED final-state radiation are found to be negligible with respect to the total uncertainty.

The correction factors are calculated assuming the predicted relative cross sections of the different Higgs production modes. The corresponding systematic uncertainty is evaluated by varying these predictions within the current experimental bounds [14]. The VBF and \( VH \) fractions are varied by factors of 0.5 and 2 with respect to the SM prediction and the \( ttH \) fraction is varied by factors of 0 and 5.

The experimental uncertainty on \( m_H \) [10] is propagated to the correction factors by studying their dependence on the Higgs boson mass.

The systematic uncertainties on the theoretical predictions include the PDF and QCD scale choices as well as the uncertainty on the \( H \rightarrow ZZ^* \) branching fraction [60]. The procedure described in Ref. [70] is used to evaluate the scale uncertainties of the predicted \( n_{jets} \) distribution.

The upper edges of the uncertainty ranges in Table 2 are in most cases due to the highest bins in the \( n_{jets} \) and \( p_{T,jet} \) distributions. The background systematic uncertainties are large in some bins due to the limited statistics in the data control regions.

8. Results

The cross section in the fiducial region described in Table 1 is

\[
\sigma_{tot}^{\text{fid}} = 2.11^{+0.53}_{-0.47} \text{(stat.)} \pm 0.08 \text{(syst.) fb.}
\]

The theoretical prediction from Ref. [69] for a Higgs boson mass of 125.4 GeV is 1.30 ± 0.13 fb.

The differential cross sections as a function of \( p_{T,H}, y_H, m_{3\ell}, |\cos \theta^*|, n_{jets}, \) and \( p_{T,jet} \) are shown in Fig. 2. For all variables and bins the total uncertainties on the cross-section measurements are
Table 3: Compatibility tests of data with POWHEG, MINLO and HRES2 ggF calculations of SM Higgs boson production. The compatibility $p$-values are obtained, as explained in the text, from the difference between $-2 \ln \Lambda$ at the best-fit value and $-2 \ln \Lambda$ with the cross sections fixed to the theory computations.

dominated by statistical uncertainties. POWHEG, MINLO and HRES2 calculations of ggF, added to VBF, $ZH/WH$ and $t\bar{t}H$ (see Section 2), are overlaid. The HRES2 calculation was developed for modelling the Higgs kinematic variables and is only used for $p_{T,H}$ and $y_{H}$. The theoretical calculations are normalized to the most precise SM inclusive cross-section predictions currently available [60].

The $p$-values quantifying the compatibility between data and predictions, computed with the method described in Section 6, are shown in Table 3. No significant discrepancy is observed.

9. Conclusion

Measurements of fiducial and differential cross sections in the $H \to ZZ^* \to 4\ell$ decay channel are presented. They are based on 20.3 $fb^{-1}$ of $pp$ collision data, produced at $\sqrt{s} = 8$ TeV centre-of-mass energy at the LHC and recorded by the ATLAS detector. The cross sections are corrected for detector effects and compared to selected theoretical calculations. No significant deviation from the theoretical predictions is observed for any of the studied variables.

24 (a) Universidade Federal do Rio De Janeiro COPPE/EE/IF, Rio de Janeiro; (b) Federal University of Juiz de Fora (UFJF), Juiz de Fora; (c) Federal University of Sao Joao del Rei (UFSJ), Sao Joao del Rei; (d) Instituto de Física, Universidade de Sao Paulo, Sao Paulo, Brazil
25 Physics Department, Brookhaven National Laboratory, Upton NY, United States of America
26 (a) National Institute of Physics and Nuclear Engineering, Bucharest; (b) National Institute for Research and Development of Isotopic and Molecular Technologies, Physics Department, Cluj Napoca; (c) University Politehnica Bucharest, Bucharest; (d) West University in Timisoara, Timisoara, Romania
27 Departamento de Física, Universidad de Buenos Aires, Buenos Aires, Argentina
28 Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom
29 Department of Physics, Carleton University, Ottawa ON, Canada
30 CERN, Geneva, Switzerland
31 Enrico Fermi Institute, University of Chicago, Chicago IL, United States of America
32 (a) Departamento de Física, Pontificia Universidad Católica de Chile, Santiago; (b) Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Chile
33 (a) Institute of High Energy Physics, Chinese Academy of Sciences, Beijing; (b) Department of Modern Physics, University of Science and Technology of China, Anhui; (c) Department of Physics, Nanjing University, Jiangsu; (d) School of Physics, Shandong University, Shandong; (e) Physics Department, Shanghai Jiao Tong University, Shanghai; (f) Physics Department, Tsinghua University, Beijing 100084, China
34 Laboratoire de Physique Corpusculaire, Clermont Université and Université Blaise Pascal and CNRS/IN2P3, Clermont-Ferrand, France
35 Nevis Laboratory, Columbia University, Irvington NY, United States of America
36 Niels Bohr Institute, University of Copenhagen, Kobenhavn, Denmark
37 (a) INFN Gruppo Collegato di Cosenza, Laboratori Nazionali di Frascati; (b) Dipartimento di Fisica, Università della Calabria, Rende, Italy
38 (a) AGH University of Science and Technology, Faculty of Physics and Applied Computer Science,
126 (a) Laboratorio de Instrumentação e Física Experimental de Partículas - LIP, Lisboa; (b) Faculdade de Ciências, Universidade de Lisboa, Lisboa; (c) Department of Physics, University of Coimbra, Coimbra; (d) Centro de Física Nuclear da Universidade de Lisboa, Lisboa; (e) Departamento de Física, Universidade do Minho, Braga; (f) Departamento de Física Teórica y del Cosmos and CAFPE, Universidad de Granada, Granada (Spain); (g) Dep Física and CEFITEC of Faculdade de Ciências e Tecnologia, Universidade Nova de Lisboa, Caparica, Portugal

127 Institute of Physics, Academy of Sciences of the Czech Republic, Praha, Czech Republic
128 Czech Technical University in Prague, Praha, Czech Republic
129 Faculty of Mathematics and Physics, Charles University in Prague, Praha, Czech Republic
130 State Research Center Institute for High Energy Physics, Protvino, Russia
131 Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom
132 Physics Department, University of Regina, Regina SK, Canada
133 Ritsumeikan University, Kusatsu, Shiga, Japan
134 (a) INFN Sezione di Roma; (b) Dipartimento di Fisica, Sapienza Università di Roma, Roma, Italy
135 (a) INFN Sezione di Roma Tor Vergata; (b) Dipartimento di Fisica, Università di Roma Tor Vergata, Roma, Italy
136 (a) INFN Sezione di Roma Tre; (b) Dipartimento di Matematica e Fisica, Università Roma Tre, Roma, Italy
137 (a) Faculté des Sciences Ain Chock, Réseau Universitaire de Physique des Hautes Energies - Université Hassan II, Casablanca; (b) Centre National de l’Énergie des Sciences Techniques Nucléaires, Rabat; (c) Faculté des Sciences Semlalia, Université Cadi Ayyad, LPHEA-Marrakech; (d) Faculté des Sciences, Université Mohammed Premier and LPTPM, Oujda; (e) Faculté des sciences, Université Mohammed V-Agdal, Rabat, Morocco
138 DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l’Univers), CEA Saclay (Commissariat à l’Energie Atomique et aux Energies Alternatives), Gif-sur-Yvette, France
139 Santa Cruz Institute for Particle Physics, University of California Santa Cruz, Santa Cruz CA, United States of America
140 Department of Physics, University of Washington, Seattle WA, United States of America
141 Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom
142 Department of Physics, Shinshu University, Nagano, Japan
143 Fachbereich Physik, Universität Siegen, Siegen, Germany
144 Department of Physics, Simon Fraser University, Burnaby BC, Canada
145 SLAC National Accelerator Laboratory, Stanford CA, United States of America
146 (a) Faculty of Mathematics, Physics & Informatics, Comenius University, Bratislava; (b) Department of Subnuclear Physics, Institute of Experimental Physics of the Slovak Academy of Sciences, Kosice, Slovak Republic
147 (a) Department of Physics, University of Cape Town, Cape Town; (b) Department of Physics, University of Johannesburg, Johannesburg; (c) School of Physics, University of the Witwatersrand, Johannesburg, South Africa
148 (a) Department of Physics, Stockholm University; (b) The Oskar Klein Centre, Stockholm, Sweden
149 Physics Department, Royal Institute of Technology, Stockholm, Sweden
150 Departments of Physics & Astronomy and Chemistry, Stony Brook University, Stony Brook NY, United States of America
151 Department of Physics and Astronomy, University of Sussex, Brighton, United Kingdom
152 School of Physics, University of Sydney, Sydney, Australia
153 Institute of Physics, Academia Sinica, Taipei, Taiwan
154 Department of Physics, Technion: Israel Institute of Technology, Haifa, Israel
155 Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University, Tel Aviv, Israel
156 Department of Physics, Aristotle University of Thessaloniki, Thessaloniki, Greece
157 International Center for Elementary Particle Physics and Department of Physics, The University of Tokyo, Tokyo, Japan
158 Graduate School of Science and Technology, Tokyo Metropolitan University, Tokyo, Japan

24
Department of Physics, Tokyo Institute of Technology, Tokyo, Japan
Department of Physics, University of Toronto, Toronto ON, Canada
TRIUMF, Vancouver BC; Department of Physics and Astronomy, York University, Toronto ON, Canada
Faculty of Pure and Applied Sciences, University of Tsukuba, Tsukuba, Japan
Department of Physics and Astronomy, Tufts University, Medford MA, United States of America
Centro de Investigaciones, Universidad Antonio Narino, Bogota, Colombia
Department of Physics and Astronomy, University of California Irvine, Irvine CA, United States of America

(a) INFN Gruppo Collegato di Udine, Sezione di Trieste, Udine; (b) ICTP, Trieste; (c) Dipartimento di Chimica, Fisica e Ambiente, Università di Udine, Udine, Italy
Department of Physics, University of Illinois, Urbana IL, United States of America
Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden
Instituto de Física Corpuscular (IFIC) and Departamento de Física Atómica, Molecular y Nuclear and Departamento de Ingeniería Electrónica and Instituto de Microelectrónica de Barcelona (IMB-CNM), University of Valencia and CSIC, Valencia, Spain
Department of Physics, University of British Columbia, Vancouver BC, Canada
Department of Physics and Astronomy, University of Victoria, Victoria BC, Canada
Department of Physics, University of Warwick, Coventry, United Kingdom
Waseda University, Tokyo, Japan
Department of Particle Physics, The Weizmann Institute of Science, Rehovot, Israel
Department of Physics, University of Wisconsin, Madison WI, United States of America
Fakultät für Physik und Astronomie, Julius-Maximilians-Universität, Würzburg, Germany
Fachbereich C Physik, Bergische Universität Wuppertal, Wuppertal, Germany
Department of Physics, Yale University, New Haven CT, United States of America
Yerevan Physics Institute, Yerevan, Armenia
Centre de Calcul de l’Institut National de Physique Nucléaire et de Physique des Particules (IN2P3), Villeurbanne, France

Faculty of Pure and Applied Sciences, University of Tsukuba, Tsukuba, Japan
Department of Physics and Astronomy, Tufts University, Medford MA, United States of America
Centro de Investigaciones, Universidad Antonio Narino, Bogota, Colombia

Yerevan Physics Institute, Yerevan, Armenia
Centre de Calcul de l’Institut National de Physique Nucléaire et de Physique des Particules (IN2P3), Villeurbanne, France

(a) Also at Department of Physics, King’s College London, London, United Kingdom
(b) Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan
c Also at Novosibirsk State University, Novosibirsk, Russia
d Also at Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom
e Also at TRIUMF, Vancouver BC, Canada
f Also at Department of Physics, California State University, Fresno CA, United States of America
g Also at Tomsk State University, Tomsk, Russia
h Also at CPPM, Aix-Marseille Université and CNRS/IN2P3, Marseille, France
i Also at Università di Napoli Parthenope, Napoli, Italy
j Also at Institute of Particle Physics (IPP), Canada
k Also at Department of Physics, St. Petersburg State Polytechnical University, St. Petersburg, Russia
l Also at Department of Financial and Management Engineering, University of the Aegean, Chios, Greece
m Also at Louisiana Tech University, Ruston LA, United States of America
n Also at Institucio Catalana de Recerca i Estudis Avancats, ICREA, Barcelona, Spain
o Also at Department of Physics, The University of Texas at Austin, Austin TX, United States of America
p Also at Institute of Theoretical Physics, Ilia State University, Tbilisi, Georgia
q Also at CERN, Geneva, Switzerland
r Also at Ochadai Academic Production, Ochanomizu University, Tokyo, Japan
s Also at Manhattan College, New York NY, United States of America
t Also at Institute of Physics, Academia Sinica, Taipei, Taiwan
u Also at LAL, Université Paris-Sud and CNRS/IN2P3, Orsay, France
v Also at Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan
w Also at Laboratoire de Physique Nucléaire et de Hautes Energies, UPMC and Université Paris-Diderot and CNRS/IN2P3, Paris, France
Also at School of Physical Sciences, National Institute of Science Education and Research, Bhubaneswar, India
Also at Dipartimento di Fisica, Sapienza Università di Roma, Roma, Italy
Also at Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia
Also at Section de Physique, Université de Genève, Geneva, Switzerland
Also at International School for Advanced Studies (SISSA), Trieste, Italy
Also at Department of Physics and Astronomy, University of South Carolina, Columbia SC, United States of America
Also at School of Physics and Engineering, Sun Yat-sen University, Guangzhou, China
Also at Faculty of Physics, M.V.Lomonosov Moscow State University, Moscow, Russia
Also at National Research Nuclear University MEPhI, Moscow, Russia
Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary
Also at Department of Physics, Oxford University, Oxford, United Kingdom
Also at Department of Physics, Nanjing University, Jiangsu, China
Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg, Germany
Also at Department of Physics, The University of Michigan, Ann Arbor MI, United States of America
Also at Discipline of Physics, University of KwaZulu-Natal, Durban, South Africa
Also at University of Malaya, Department of Physics, Kuala Lumpur, Malaysia
