CURRENT AND FORMER RELATIONSHIP WITH EX-PARTNER
HOW IS IT RELATED TO PSYCHOLOGICAL ADAPTATION TO GREY DIVORCE?

THEORETICAL BACKGROUND AND RESEARCH AIMS
The current and former relationship with the ex-partner can be a resource but also a chronic stressor affecting psychological adaptation to divorce. Little research has been carried out on this topic especially regarding in breakups after a long-term relationship.

Aims and Hypotheses:
Considering this gap and based on the divorce-stress-adjustment perspective (Amato, 2000), we want
(1) to explore how quantity and quality of current contact to the ex-partner is associated with psychological adaptation (i.e., life satisfaction and depressive symptoms) across three waves (2012, 2014, 2016).
(2) to examine the association of satisfaction with prior relationship and reason of separation with the (2a) quality of the current relationship and with (2b) psychological adaptation at t1. We consider intra-individual and socio-demographic variables.

We hypothesize that
• (H1a) independent of time, being in conflicted contact with the ex-partner is related to poorer adjustment (higher depressive symptoms, lower life satisfaction) (cf. chronic strain approach).
• high satisfaction with the ex-relationship is related to (H2a) better quality of contact to the ex-partner and to (H2b) better psychological adaptation at t1.
• Regarding separation reason, we expect that infidelity of the ex-partner is related to (H3a) poorer psychological adaptation and (H3b) lower quality of contact at t1.

METHODS

Study description and statistical analyses
• Data stem from the longitudinal, survey-based study relationships in later life with three measurement points (2012, 2014, 2016), which are a part of the Swiss National Centre of Competence in Research ‘LIVES’ (funded by the Swiss National Science Foundation).
• Sample: 411 persons aged 45 – 65 years (M = 51.17 years, SD = 6.68) at t1 (117 men; 294 women); breakup after 21.60 years (SD = 8.1). Time since separation: 2.74 years (SD = 2.76). 70% (n = 279) were still in contact with their ex-partner at t3.
• Statistical analyses were carried out with longitudinal structural equation modeling (Mplus).

RESULTS

Quantity of contact with the ex-partner was not related to depressive symptoms nor to life satisfaction (all p’s > .05).

Quality of contact with the ex-partner, former relation and adaptation to breakup

DISCUSSION

Our results demonstrate that being in contact or not (and quantity of contact) to the ex-partner was not related to psychological adaptation. However, in line with our hypotheses, quality of current relationship to the ex-partner was significantly related to adaptation at all three waves, even when new partnership status, personality traits and socio-demographic variables were considered. It can therefore be assumed that current contact to the ex-partner can be a long-term stressor – or in case of high contact quality a resource – for psychological adaptation.

In contrast to our expectations, prior marital satisfaction and separation reasons were not predictive for psychological adaptation at t1, but of current relationship quality at t1 (higher dissatisfaction with ex-relationship and ex-partner infidelity was related to worse quality of the current relationship).

Our results support the crisis approach: participants reported better psychological adaptation over the three waves, and more time passed since separation was marginally related to lower scores in depressive symptoms.

In line with prior research, personality variables (i.e., lower scores in neuroticism, higher scores in extraversion and agreeableness) and being in a new relationship predicted better psychological adaptation.

Knowledge about variables accounting for inter-individual differences is important to gain a deeper understanding of the process of adaptation to separation after long-term relationships and for therapeutic intervention.
