High resolution X-ray (XRD) and polarized neutron diffractions (PND) are routinely used to model charge and spin densities of localized electrons, while inelastic Compton scattering (ICS) is a valuable mean for determining delocalized electrons. Our objective is to construct a unique electron density model common to these three experimental data sets. We have demonstrated that a joint refinement of a multipolar model based on polarized neutron and X-ray diffraction data is possible and brings more insight in the electron distribution [1]. The inclusion of ICS data implies to go beyond the atom centered model to take into account bicentric terms. As the multipolar model is thus no more adapted, a new model based on atomic orbitals under development will be discussed and applied to a YTiO3 perovskite crystal. This compound is ferromagnetic at low temperature (below 29K), suggesting that a single d electron (0.84mB/mol) mainly localized on the Ti atom gives rise to the magnetic interactions. 

Keywords: charge spin densities, x ray diffraction, polarised neutron diffraction, magnetic compton scattering, joint refinement, magnetic materials

The structures of new compound [CuX(pyz)]2(BF4) with X = Cl and Br and pyz = pyrazine were determined by single crystal X-ray diffraction. These tetragonal compounds crystallize in space group P4/nbm. They are built from [CuX(pyz)]21 layers which are connected by X ions along the c-axis. Charge is compensated by BF4 ions in the voids of the 3D coordination compound. The antiferromagnetic interactions between the Cu2+ ions are mainly two-dimensional (2D) located within the [CuX(pyz)]21 layers. This results in a broad maximum of the magnetic susceptibility around 9 K. Towards lower temperature a kink is observed at 4 K which indicates long-range 3D magnetic order. The magnetic unit cell is doubled along the c-axis (k = 0, 0, 1/2) and the ordered magnetic moment amounts to μ = 0.76(8) μ/Cu2+ at 1.5 K. The moments are antiferromagnetically coupled along the b- and c-axes. Long-range 3D magnetic order is observed below Tc = 3.9(1) K. A fit of a 2D Heisenberg model to the magnetic susceptibility data results in J_2 = 9.6 K.
