At the age of 30, a young father noticed a low oxygen saturation while playing with the finger pulse oximeter of his child awaiting surgery. Since he was completely asymptomatic, he did not seek medical attention. At the age of 51, he was referred to the outpatient clinic of our pulmonary department after detection of a severe nocturnal "hypoxemia". Previous evaluation for obstructive sleep apnea by nocturnal respiratory polygraphy because of snoring revealed a significantly decreased average oxygen saturation (SpO<sub>2</sub> 71%). The former smoker (25 packyears) was known for allergic/seasonal bronchial asthma with occasional use of an inhaled short-acting  $\beta$ -2selective adrenergic agonist (terbutalin) preceding physical activity. He denied having respiratory symptoms like dyspnea, cough, thoracic pain, or infections, and did not experience a decline of his physical performance.

The patient presented to our outpatient clinic with a significantly decreased peripheral  $O_2$  saturation of 76–82% while breathing ambient air, which was measured by different pulse oximeters (Fig. 1). SpO<sub>2</sub> rose only to 86% while breathing 7 L/min supplemental oxygen via nasal cannula. Other vital signs were normal (blood pressure 124/68 mm Hg, heart rate 86 beats/min, respiratory rate 16/min) and the patient showed no signs of respiratory

	Results	Normal range
Pulse oximetry		
SpO <sub>2</sub>	76-82%	>92%
Arterial blood gas analysis		
SaO <sub>2</sub>	89%	93-98%
paO <sub>2</sub>	10.9 kPa (82 mm Hg)	9.5–13.9 kPa (71–104 mm Hg)
p50	5.3 kPa (40 mm Hg)	3.2–3.7 kPa (24–28 mm Hg)
paCO <sub>2</sub>	5.1 kPa (38 mm Hg)	4.7–6.1 kPa (35–46 mm Hg)
pH	7.45	7.35-7.45
Standard bicarbonate	26 mmol/L	18–29 mmol/L
Further analysis		
Hemoglobin	138 g/L	135–168 g/L
Reticulocytes	$2.2\%, 107 \times 10^9/L$	$0.8 - 2.2\%, 40 - 100 \times 10^9/L$
MCHC	318 g/L	320-360 g/L
MCV	89 fl	80–98 fl
MCH	28 pg	27-33 pg
LDH	183 U/L	<480 U/L
Bilirubin	11 μmol/L	<17 µmol/L
Haptoglobin	0.44 g/L	0.3–2 g/L
Erythropoietin	24.8 mU/mL	4.3–29.0 mU/mL

**Table 1.** Results of pulse oximetry, arterial blood gas analysis and further laboratory analyses

89% predicted) or airway obstruction (FEV<sub>1</sub>/FVC 75%, FEV<sub>1</sub> 3.16 L, 89% predicted), but signs of small airway disease (MEF50 66% predicted). The diffusing capacity was above normal range (DLCO 126% predicted). Spiroergometry confirmed a normal cardiopulmonary performance (VO<sub>2</sub>max 23.5 mL/min/kg, 95% predicted) with a

mildly diminished oxygen pulse (19.6 mL, 76% predicted), decreased slope and early plateau. Arterial blood gas analysis measured an oxygen saturation (SaO<sub>2</sub>) of 89%,  $paO_2$  10.9 kPa (82 mm Hg) and p50 5.3 kPa (40 mm Hg). Table 1 lists the laboratory results.

What is your diagnosis?

## **Diagnosis: Hemoglobinopathy Cheverly**

Due to the discrepancy between invasively and noninvasively measured SO<sub>2</sub>, evaluation for an abnormal hemoglobin was performed. Conventional hemoglobin electrophoresis (alkaline cellulose acetate) was normal. Alpha-2 hemoglobin [3.2% (normal range 1.8–3.2%)] and fetal hemoglobin [0.5% (normal range <1.5%)] were not increased. High-pressure liquid chromatography showed a small peak at 4.52 min (Fig. 2) leading to the suspicion of Hb Constant Spring, the most common nondeletional  $\alpha$ -thalassemia [1]. However, performing Sanger sequencing of the  $\alpha$ -globin gene cluster, neither Hb Constant Spring nor any other point mutation could be detected.

The oxygen saturation curve assessed by spectrophotometer (Fig. 3) confirmed the elevated p50 (4.4 kPa/32.7 mm Hg), which indicates a reduced oxygen affinity of the hemoglobin. Finally, by sequencing the  $\beta$ -globin gene (Fig. 4), a heterozygous mutation c.137 T>C, previously described as hemoglobin Cheverly, was detected.

# Discussion

Impairment in gas exchange or ventilation/perfusion mismatches are the most common causes of low SpO<sub>2</sub> in daily routine in pulmonary medicine. Potential sources of error in pulse oximetry are poor peripheral perfusion, skin pigmentation, nail polish, motion artefacts and interfering ambient light. Although anemia does not change the ratio of oxyhemoglobin to deoxyhemoglobin, severe anemia can cause underestimation of SpO<sub>2</sub>, especially in hypoxemic subjects, mainly because pulse oximeters are calibrated on healthy subjects without anemia [2, 3]. In general, small amounts of COHb and MetHb are not detected by pulse oximetry and lead to overestimation of SpO<sub>2</sub>, if present [4]. Variant hemoglobins are rare causes of falsely low pulse oximetry readings and are usually taken into consideration only after extensive assessment for respiratory and cardiac diseases, exclusion of MetHb, SulfHb, COHb, and other factors disturbing the performance of pulse oximeters [5].

The true  $SaO_2$  is measured by arterial blood gas analysis (applying more than 100 wavelengths). Discordant  $SaO_2$  and  $SpO_2$  values (defined as >5% difference) occur in some variant hemoglobins, with underestimation of the true  $SaO_2$  because these hemoglobins have unusual absorption spectra for which the two wave pulse oximeters are not designed [6]. If  $SaO_2$  and  $SpO_2$  are concor-

**Fig. 2.** Cation-exchange high-pressure liquid chromatogram of the patient's blood sample showing an abnormal peak after 4.52 min retention time (arrow).

dantly low (<5% difference), focus should be on the amount of oxygen dissolved in arterial blood (paO<sub>2</sub>). Physiologically, the oxygen saturation increases in an Sshaped curve as paO<sub>2</sub> rises. This curve can shift to the right with increase in temperature, lower pH (acidity) and higher concentrations of CO<sub>2</sub> or 2,3-bisphosphoglycerate [7]. An increased p50 indicates a shift of the curve to the right and towards lower oxygen affinity, which enables the hemoglobin to unload more oxygen in the peripheral tissues. Therefore, at normal paO<sub>2</sub>, the tissue oxygenation of hemoglobin Cheverly is not affected, despite a lowered SaO<sub>2</sub>.

Hemoglobinopathies are common hereditary diseases and more than 1,000 mutations of the globin chains are described. The quantitative thalassemia syndromes are the most frequent mutations and prevalence can be as high as 95% in certain populations. Most of the qualitative hemoglobinopathies have frequencies below 1% and can be associated with various or even no clinical manifestations [8]. In 1982 and 1983, an elderly Italian male with cyanotic heart disease [9] and an anemic female in Baltimore [10] were the first patients described with the Cheverly variant hemoglobin. In a German observational study, over a period of four decades, only 9 patients within hemoglobin Cheverly have been found [11]. A point mutation in the  $\beta$ -globin gene (single base modification) with replacement of thymidin by cytosin (c.137 T>C) and consecutive replacement of the amino acid phenylalanine by serine (p.45 Phe>Ser) weakens the heme-globin inter-

**Fig. 3.** Oxygen dissociation curves of normal (healthy donor, green) and low oxygen affinity (patient, blue) hemoglobin measured by dual wavelength spectrophotometer (HemoAnalyzer<sup>®</sup>, TCS Medical Products, USA). As the p50 value increases (blue curve), the oxygen affinity of hemoglobin decreases (right shift) compared to the healthy donor (green curve).

**Fig. 4.** Sanger sequencing of the  $\beta$ -globin gene cluster. This cutout of the  $\beta$ -globin gene Sanger sequencing of the index patient illustrates the detected base substitution (T>C, indicated by Y) at position codon 137 (highlighted with a box). The reference sequence (HBB) is shown at the top and the four DNA bases (T, C, A, G) are

represented by different colors. Further, the location of the mutation in the  $\beta$ -globin gene cluster is illustrated by the boxes above the sequences showing part of intron 1 and 2 as well as exon 2, where the described mutation is indicated with a red bar.

Asymptomatic "Hypoxemia"?

Respiration 2016;92:420–424 DOI: 10.1159/000451030 action and can cause instability of the affected  $\beta$ -globin chain. This can cause a mild hemolytic anemia in some of the cases. The low oxygen affinity of hemoglobin Cheverly causes the slightly decreased SaO<sub>2</sub> in the presence of a normal paO<sub>2</sub> measurement. In addition, the abnormal absorption spectrum of hemoglobin Cheverly explains the discordantly lower SpO<sub>2</sub> compared with SaO<sub>2</sub> [12, 13].

# **Conclusion and Clinical Implications**

In rare cases, a variant hemoglobin can be the reason for falsely low SpO<sub>2</sub> readings and has to be considered in patients without any cardiopulmonary symptoms. Examination by electrophoresis and high-pressure liquid chromatography might not be sufficient to detect hemoglobinopathy, and sequencing of the globin genes might be necessary. Variant hemoglobins that have an abnormal absorption spectrum should be suspected if  $SpO_2$  and  $SaO_2$  are discordant. Low-affinity hemoglobin is present if p50 is elevated. In the case of hemoglobin Cheverly, both factors contribute to the abnormal constellation of decreased  $SaO_2$  and  $SpO_2$ . Hemoglobin Cheverly is not expected to cause symptoms, but counselling of the affected individuals and equipping them with emergency cards can avoid unnecessary diagnostic and therapeutic procedures in case of routine medical interventions or medical emergencies, where the attending physician has to know about the inaccurate pulse oximeter reading. Further, we suggest a screening of family members simply by measuring  $SpO_2$  with a pulse oximeter.
